# Power Efficient Positioning for Visible Light Systems via Chance Constrained Optimization

Onurcan Yazar, Musa Furkan Keskin, and Sinan Gezici

Abstract—The problem of minimizing total power consumption in light-emitting diode (LED) transmitters is investigated for achieving power efficient localization in a visible light communication and positioning (VLCP) system. A robust power allocation approach based on stochastic uncertainties is proposed for total power minimization in the presence of localization accuracy, power, and illumination constraints. Specifically, the power consumption minimization problem is formulated under a chance constraint on the probability of Cramér-Rao lower bound (CRLB) exceeding a tolerable limit, which is a computationally intractable constraint. The sphere bounding method is used to propose a safe convex approximation to this intractable constraint, which makes the resulting problem suitable for standard convex optimization tools. Numerical results demonstrate the advantages of the proposed robust solution over the nonrobust solution and uniform power allocation in the presence of stochastic uncertainty.

*Index Terms*- Visible light communication and positioning (VLCP), robust design, power efficiency, chance constrained programming, convex optimization.

#### I. INTRODUCTION

Visible light communication (VLC) applications based on light-emitting diodes (LEDs) have become widespread in recent years due to the advances in LED technologies as well as their advantages over current wireless communication schemes [1]–[3]. VLC-based designs come into prominence not only by their multi-purpose utilization capability along with indoor illumination but also by providing high data rates, low multipath fading, and no requirement of a licensed spectrum [4], [5].

Visible light positioning (VLP) systems, which involve the usage of visible light systems to accomplish localization tasks, have also become an intriguing area of research [6]–[8]. In VLP systems, the location of a VLC receiver can be estimated by utilizing the visible light signals transmitted by anchor nodes, which are LED transmitters with known locations [9].

Our main objective in this work is to design power efficient VLP systems by minimizing the total power consumption in LED transmitters while maintaining a desired level of localization performance under practical constraints. Although power and resource allocation has been investigated extensively for VLC systems (e.g., [10]–[16]), it has been considered only in a few studies for VLP systems [17]–[20]. In [17], an orthogonal frequency division multiple access (OFDMA) based visible light system with both communication and positioning capabilities is considered, and a power allocation algorithm

is proposed to reduce the positioning error. The work in [18] focuses on a multi-user visible light communication and positioning (VLCP) system, and proposes a joint subcarrier and power allocation approach to maximize the sum rate under constraints on minimum data rates and localization accuracy of users. In [20], optimal and robust power allocation strategies are examined to improve localization performance of VLP systems and to address the problem of minimum power consumption in the presence of uncertainty modeled by deterministic norm-bounded errors. In this letter, we propose the problem of minimum total power consumption for LED transmitters in a VLP system in which a stochastic approach is embraced in modeling the uncertainties in the localization parameters. To our knowledge, the total power minimization problem in the presence of stochastic uncertainty has not been considered before in the VLP literature, which is an important problem as the assumption of deterministically bounded errors may not be practical in general [21], [22].

The minimum total power consumption problem in the case of deterministic norm-bounded uncertainty is solved in [20] through an upper constraint on the Cramér-Rao lower bound (CRLB) for the localization error, which yields a convex optimization problem . However, in the case of stochastic uncertainty considered in this work, the fact that the unbounded parameter uncertainties come into the problem precludes the use of a worst-case upper bound on the CRLB [21], [22]. For such a case, we propose to formulate the robust design problem as a chance constrained optimization problem, in which a probabilistic constraint on the *localization accuracy* outage probability is established [23], [24]. We propose to solve this problem by proving that this probabilistic constraint can conservatively be approximated by a convex constraint via the sphere bounding method. This solution strategy is shown to satisfy any constraint on the localization accuracy outage probability as opposed to the non-robust approach and the uniform power allocation strategy. The main contributions of this work over [20] are related to the consideration of a probabilistic constraint on the localization accuracy for the minimum total power consumption problem in a VLP system and the proposed solution approach based on the sphere bounding method.

### II. SYSTEM MODEL

We consider a VLP setup in which the location of a VLC receiver is estimated by utilizing the signals sent by  $N_L$  LED transmitters. As the multipath fading effect is not significant in visible light systems compared to RF-based systems, only the line-of-sight (LOS) path between each LED transmitter and

O. Yazar and S. Gezici are with the Department of Electrical and Electronics Engineering, Bilkent University, 06800, Ankara, Turkey (e-mails: {onurcan, gezici}@ee.bilkent.edu.tr). M. F. Keskin is with the Department of Electrical Engineering, Chalmers University of Technology, 41296, Gothenburg, Sweden (e-mail: furkan@chalmers.se).

the VLC receiver is considered [6], [25], [26]. The receiver is assumed to be able to process the signals sent by different LED transmitters individually by following a multiple access protocol (e.g., frequency-division multiple access). Then, the received (electrical) signal at the output of the photodetector at the VLC receiver due to the signal transmitted by the *i*th LED transmitter can be modeled as [11], [27]<sup>1</sup>

$$r_i(t) = \alpha_i R_p s_i(t - \tau_i) + \eta_i(t) \tag{1}$$

for  $i \in \{1, \ldots, N_L\}$  and  $t \in [T_{1,i}, T_{2,i}]$ , where  $T_{1,i}$  and  $T_{2,i}$  are the starting and the ending time instants for VLC receiver's observation of the signal transmitted by the *i*th LED transmitter,  $\alpha_i$  is the optical channel attenuation factor between the *i*th LED transmitter and the VLC receiver,  $R_p$  is the responsivity of the photodetector at the VLC receiver,  $s_i(t)$  is the transmitted signal of the *i*th LED transmitter,  $\tau_i$  is the time-of-arrival (TOA) of the signal arriving from the *i*th LED transmitter, and  $\eta_i(t)$ 's are independent zero-mean additive white Gaussian noise processes each having a spectral density level of  $\sigma^2$  (with the independence stemming from the multiple access protocol).

The TOA in (1) can be determined by

$$\tau_i = \frac{||\boldsymbol{l}_{\rm r} - \boldsymbol{l}_{\rm t}^i||}{c} + \delta_i \tag{2}$$

where the positions of the VLC receiver and the *i*th LED transmitter are denoted by  $l_r = [l_{r,1} \ l_{r,2} \ l_{r,3}]^T$  and  $l_t^i = [l_{t,1}^i \ l_{t,2}^i \ l_{t,3}^i]^T$  respectively, *c* denotes the speed of light,  $|| \cdot ||$  specifies the Euclidean norm, and  $\delta_i$  stands for the clock offset between the VLC receiver and the *i*th LED transmitter, which is equal to zero in synchronous systems and regarded as an unknown parameter in asynchronous systems [27].

The optical channel attenuation factors  $\alpha_i$  given in (1) can be expressed through the Lambertian model as [28]

$$\alpha_i = \frac{S(m_i + 1)(\boldsymbol{l}_{t}^{i} - \boldsymbol{l}_{r})^T \boldsymbol{n}_{r}}{2\pi \left( (\boldsymbol{l}_{r} - \boldsymbol{l}_{t}^{i})^T \boldsymbol{n}_{t}^{i} \right)^{-m_i} ||\boldsymbol{l}_{r} - \boldsymbol{l}_{t}^{i}||^{m_i + 3}}$$
(3)

where S is the area of the photodetector at the VLC receiver,  $m_i$  stands for the Lambertian order for the *i*th LED, and  $n_r = [n_{r,1} \ n_{r,2} \ n_{r,3}]^T$  and  $n_t^i = [n_{t,1}^i \ n_{t,2}^i \ n_{t,3}^i]^T$  correspond to the orientation vectors for the VLC receiver and the *i*th LED transmitter, respectively. In this configuration, it is assumed that parameters S and  $n_r$  are known by the VLC receiver (e.g., via measurements from a gyroscope) and the parameters related to the LED transmitters (i.e.,  $m_i$ ,  $l_t^i$ , and  $n_t^i$ ) can be acquired by the VLC receiver through communications with each of the LED transmitters.

#### III. PROBLEM FORMULATION AND PROPOSED APPROACH

In this section, we first formulate a robust total power minimization problem for VLP systems under a chance constraint related to the localization accuracy of the VLC receiver. Then, we apply the sphere bounding method to provide a lowcomplexity solution to the proposed problem.

#### A. Assessment of Localization Performance

In order to quantify the localization performance of the VLP system, the CRLB for the location estimation error is chosen as the performance metric. The main motivations behind the use of the CRLB metric are that the maximum likelihood (ML) estimator achieves a very close performance to the CRLB at high signal-to-noise ratios and that CRLB expressions commonly facilitate theoretical investigations and analyses [20].

Among other factors, the CRLB is related to the transmitted signals  $s_i(t)$  utilized in the localization of the VLC receiver. As in [20], the transmitted signals can be represented in terms of base signals  $\tilde{s}_i(t)$  as

$$s_i(t) = \sqrt{P_i}\,\widetilde{s}_i(t) \tag{4}$$

for  $i \in \{1, \ldots, N_L\}$ , where the non-negative base signal represents the normalized version of the transmitted signal such that it has a unit power, i.e., it satisfies  $\int_0^{T_{s,i}} (\tilde{s}_i(t))^2 dt = T_{s,i}$ , where  $T_{s,i}$  denotes the duration of the transmitted signal. In other words, in this configuration,  $P_i$  indicates the electrical transmit power of the *i*th LED transmitter. Then, we define

$$\mathbf{p} \triangleq \left[P_1 \cdots P_{N_L}\right]^T \tag{5}$$

which is used as the main optimization variable for the minimum total power consumption problem. As shown in (4), our power optimization framework relies on scaling the non-negative base signals  $\tilde{s}_i(t)$  by parameters  $\sqrt{P_i}$ , which implies that adjusting **p** in (5) affects both the DC and AC parts of the LED signals.

The CRLB on the variance of any unbiased estimator  $l_r$  for the VLC receiver location  $l_r$  is expressed as [27]

$$\mathbb{E}\left\{||\hat{\boldsymbol{l}}_{\mathrm{r}} - \boldsymbol{l}_{\mathrm{r}}||^{2}\right\} \ge \operatorname{trace}\left\{\mathbf{J}^{-1}(\mathbf{p})\right\}$$
(6)

where J(p) is the Fisher information matrix (FIM), which is computed by [20]

$$\mathbf{J}(\mathbf{p}) = (\mathbf{I}_3 \otimes \mathbf{p})^T \mathbf{\Gamma} \,. \tag{7}$$

In (7),  $I_3$  is the  $3 \times 3$  identity matrix,  $\otimes$  denotes the Kronecker product, and

$$\boldsymbol{\Gamma} \triangleq \begin{bmatrix} \boldsymbol{\gamma}_{1,1} & \boldsymbol{\gamma}_{1,2} & \boldsymbol{\gamma}_{1,3} \\ \boldsymbol{\gamma}_{2,1} & \boldsymbol{\gamma}_{2,2} & \boldsymbol{\gamma}_{2,3} \\ \boldsymbol{\gamma}_{3,1} & \boldsymbol{\gamma}_{3,2} & \boldsymbol{\gamma}_{3,3} \end{bmatrix} \in \mathbb{R}^{3N_L \times 3}$$
(8)

with

$$\boldsymbol{\gamma}_{k_1,k_2} \triangleq \left[ \gamma_{k_1,k_2}^{(1)} \dots \gamma_{k_1,k_2}^{(N_L)} \right]^T \in \mathbb{R}^{N_L}$$
(9)

<sup>&</sup>lt;sup>1</sup>The signal model in (1) is in compliance with Eq. (3) of [11] for the case of single-color LEDs.

for  $k_1, k_2 \in \{1, 2, 3\}$  [20].  $\gamma_{k_1, k_2}^{(i)}$  in (9) is as described in [20, App. A], which is also stated below for convenience:

$$\begin{split} \gamma_{k_{1},k_{2}}^{(i)} &= \begin{cases} \gamma_{k_{1},k_{2}}^{(i),\mathrm{syn}}, & \text{if synchronous VLP system} \\ \gamma_{k_{1},k_{2}}^{(i),\mathrm{asy}}, & \text{if asynchronous VLP system} \end{cases} \\ \gamma_{k_{1},k_{2}}^{(i),\mathrm{syn}} &\triangleq \frac{R_{p}^{2}}{\sigma^{2}} \left( E_{2}^{i} \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k_{1}}} \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k_{2}}} + E_{1}^{i} \alpha_{i}^{2} \frac{\partial \tau_{i}}{\partial l_{\mathrm{r},k_{1}}} \frac{\partial \tau_{i}}{\partial l_{\mathrm{r},k_{2}}} \\ &- E_{3}^{i} \alpha_{i} \left( \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k_{1}}} \frac{\partial \tau_{i}}{\partial l_{\mathrm{r},k_{2}}} + \frac{\partial \tau_{i}}{\partial l_{\mathrm{r},k_{1}}} \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k_{2}}} \right) \right) \\ \gamma_{k_{1},k_{2}}^{(i),\mathrm{asy}} &\triangleq \frac{R_{p}^{2}}{\sigma^{2}} \left( E_{2}^{i} - \frac{(E_{3}^{i})^{2}}{E_{1}^{i}} \right) \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k_{1}}} \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k_{2}}} \\ E_{1}^{i} &\triangleq \int_{0}^{T_{s,i}} \left( \tilde{s}_{i}'(t) \right)^{2} dt, \quad E_{2}^{i} &\triangleq \int_{0}^{T_{s,i}} \left( \tilde{s}_{i}(t) \right)^{2} dt \\ E_{3}^{i} &\triangleq \int_{0}^{T_{s,i}} \tilde{s}_{i}(t) \tilde{s}_{i}'(t) dt, \quad \frac{\partial \tau_{i}}{\partial l_{\mathrm{r},k_{1}}} = \frac{l_{\mathrm{r},k} - l_{\mathrm{t},k}^{i}}{c \| l_{\mathrm{r}} - l_{\mathrm{t}}^{i} \| } \\ \frac{\partial \alpha_{i}}{\partial l_{\mathrm{r},k}} &= -\frac{(m_{i}+1)S}{2\pi} \left( \frac{\left( (l_{\mathrm{r}} - l_{\mathrm{t}}^{i})^{T} \mathbf{n}_{\mathrm{t}}^{i} \right)^{m_{i}-1}}{\| l_{\mathrm{r}} - l_{\mathrm{t}}^{i} \|^{m_{i}+3}}} \\ \times \left( m_{i} n_{\mathrm{t},k}^{i} (l_{\mathrm{r}} - l_{\mathrm{t}}^{i})^{T} \mathbf{n}_{\mathrm{r}} + n_{\mathrm{r},k} (l_{\mathrm{r}} - l_{\mathrm{t}}^{i})^{T} \mathbf{n}_{\mathrm{t}}^{i} \right) \\ - \frac{(m_{i}+3)(l_{\mathrm{r},k} - l_{\mathrm{t},k}^{i})}{\| l_{\mathrm{r}} - l_{\mathrm{t}}^{i} \|^{m_{i}+5}} \left( (l_{\mathrm{r}} - l_{\mathrm{t}}^{i})^{T} \mathbf{n}_{\mathrm{t}}^{i} \right)^{m_{i}} \left( l_{\mathrm{r}} - l_{\mathrm{t}}^{i})^{T} \mathbf{n}_{\mathrm{t}}^{i} \right)^{m_{i}} \right) \\ \end{array}$$

where  $\tilde{s}'_i(t)$  denotes the derivative of  $\tilde{s}_i(t)$ .

Remark 1: From the preceding expressions, it is noted that, for a given power vector **p**, the CRLB is determined by matrix  $\Gamma$ , which depends on the VLP system parameters, consisting of  $R_p$ , S,  $\sigma^2$ ,  $l_r$ ,  $n_r$ ,  $l_t^i$ ,  $n_t^i$ ,  $m_i$ ,  $E_1^i$ ,  $E_2^i$ , and  $E_3^i$  for  $i \in \{1, \ldots, N_L\}$ . In general, the knowledge of the receiver related parameters except for  $l_r$ ; namely,  $R_p$ , S,  $\sigma^2$ , and  $n_{\rm r}$ , can be available at the VLC receiver or obtained by it via previous observations or sensor (e.g., gyroscope) measurements. Similarly, the knowledge of the transmitter related parameters,  $l_t^i$ ,  $n_t^i$ ,  $m_i$ ,  $E_1^i$ ,  $E_2^i$ , and  $E_3^i$ , are available at the LED transmitters. Since the knowledge of some system parameters (e.g.,  $n_r$ ) may be imperfect and  $l_r$  is unknown in general, it is not possible to know  $\Gamma$  perfectly. Hence, a robust approach should be taken by employing a suitable uncertainty model for the information about  $\Gamma$ . 

#### B. Practical Constraints on LED Powers

Before the formulation of the optimization problem, the constraint sets on the LED powers should be specified. These limitations are due to practical concerns such as hardware requirements and desired ambient illumination levels.

(i) Individual bounds on each of the allocated LED powers exist for guaranteeing the operation of each LED in the linear region so as to provide efficient optical energy conversion and also to prevent self-heating resulting from high currents flowing through the LEDs. Thus, the constraint set P<sub>1</sub> in [20, Eq. 12] must be considered, which is stated as follows:

$$\mathcal{P}_{1} \triangleq \{ \mathbf{p} \in \mathbb{R}^{N_{\mathrm{L}}} : \mathbf{p}_{\mathrm{lb}} \preceq \mathbf{p} \preceq \mathbf{p}_{\mathrm{ub}} \}$$
(10)

where  $\mathbf{p}_{lb} \in \mathbb{R}^{N_L}$  and  $\mathbf{p}_{ub} \in \mathbb{R}^{N_L}$  represent, respectively, the lower and upper bounds on  $\mathbf{p}$  in (5).

(*ii*) The fact that VLP systems are used for illumination purposes in indoor scenarios may necessitate particular locations over the region to have illumination limitations. Therefore, we have the constraint set  $\mathcal{P}_3$  specified in [20, Eq. 17], which is expressed as

$$\mathcal{P}_3 \triangleq \{ \mathbf{p} \in \mathbb{R}^{N_{\mathrm{L}}} : \mathcal{I}_{\mathrm{ind}}(\mathbf{x}_{\ell}, \mathbf{p}) \ge \widetilde{\mathcal{I}}_{\ell}, \ \ell = 1, \dots, L \}$$
(11)

with L denoting the number of locations at which the illuminance constraint should be satisfied and  $\tilde{\mathcal{I}}_{\ell}$  being the illuminance constraint for location  $\mathbf{x}_{\ell}$ . In addition,  $\mathcal{I}_{ind}(\mathbf{x}_{\ell}, \mathbf{p})$  in (11) is given by [20]

 $\mathcal{I}_{\mathrm{ind}}(\mathbf{x}_{\ell}, \mathbf{p}) = \sum_{i=1}^{N_{\mathrm{L}}} \sqrt{P_i} \phi_i(\mathbf{x}_{\ell})$ 

with

$$\phi_{i}(\mathbf{x}) = \frac{(m_{i}+1)\kappa_{i}\widetilde{E}_{i}^{\text{opt}}\left[(\mathbf{x}-\boldsymbol{l}_{t}^{i})^{T}\boldsymbol{n}_{t}^{i}\right]^{m_{i}}(l_{t,3}^{i}-x_{3})}{2\pi\|\mathbf{x}-\boldsymbol{l}_{t}^{i}\|^{m_{i}+3}}$$
(12)

where  $\widetilde{E}_i^{\text{opt}} \triangleq \int_0^{T_{s,i}} \widetilde{s}_i(t) dt / T_{s,i}$  and  $\kappa_i$  represents the luminous efficacy (lm/W) of the *i*th LED [29]. It is noted that the illumination constraints are related to the DC levels of the transmitted signals.

(*iii*) In some scenarios, an additional average illuminance constraint over a certain region (e.g., the entire indoor region) may exist. In order to handle such situations, we induce the constraint set  $\mathcal{P}_4$  in [20, Eq. 19], which can be stated as

$$\mathcal{P}_{4} \triangleq \left\{ \mathbf{p} \in \mathbb{R}^{N_{\mathrm{L}}} : \sum_{i=1}^{N_{\mathrm{L}}} \frac{\sqrt{P_{i}}}{|\mathcal{A}|} \int_{\mathcal{A}} \phi_{i}(\mathbf{x}) d\mathbf{x} \ge \widetilde{\mathcal{I}}_{\mathrm{avg}} \right\}$$
(13)

where  $\mathcal{A}$  denotes the region,  $|\mathcal{A}|$  is the volume of  $\mathcal{A}$ ,  $\phi_i(\mathbf{x})$  is as in (12), and  $\widetilde{\mathcal{I}}_{avg}$  represents the average illuminance constraint.

## C. Robust Minimization of Total Power Consumption via Chance Constrained Programming

The aim is to perform optimal power allocation among the LED transmitters in order to minimize their total power consumption under a constraint on the localization accuracy of the VLC receiver as well as the practical constraints in Sec. III-B. This power allocation operation is performed by a central controller (e.g., a micro-controller) that sets the parameters of the LED transmitters [19]. Since the knowledge of the system parameters that determine  $\Gamma$  (hence, the CRLB) may not be available at the central controller (Remark 1), the power allocation should be performed in the presence of imperfect knowledge. Therefore, a robust constraint should be considered for the localization accuracy of the VLC receiver. If upper and lower bounds on the error related to each system parameter are known, a deterministic norm-bounded uncertainty model as in [20] can be employed for  $\Gamma$ . However, such knowledge may not always be available due to stochastic nature of error sources in measuring some parameters. As an alternative approach, we propose a stochastic uncertainty model in this work. Namely, we model the uncertainty in the measurement of the actual localization parameter matrix  $\Gamma$ by considering the measured value of  $\Gamma$  as  $\tilde{\Gamma} = \Gamma + \Delta \Gamma$ , where  $\Delta \Gamma$  represents the stochastic error matrix. The fact that the measured matrix  $\tilde{\Gamma}$  is obtained as a result of the noisy estimates of the true matrix  $\Gamma$  leads us to consider the error matrix  $\Delta \Gamma$  having a certain probabilistic structure [30]–[33]. Similar to RF [23], [30] and visible light [21], [22] based models, we can model the free entries<sup>2</sup> in  $\Delta \Gamma \in \mathbb{R}^{3N_L \times 3}$  as independent and identically distributed zero mean Gaussian random variables with variance  $\sigma_e^2$ , i.e.,  $\Delta \Gamma_{jk} \sim \mathcal{N}(0, \sigma_e^2)$ , where  $\Delta \Gamma_{jk}$  is the (j, k)th entry in  $\Delta \Gamma$ for  $(j, k) \in \{1, \ldots, 3N_L\} \times \{1, 2, 3\}$ . This can alternatively be stated as

$$\begin{bmatrix} \mathbf{v}_d(\mathbf{\Delta}\mathbf{\Gamma}) \\ \mathbf{v}_{od}(\mathbf{\Delta}\mathbf{\Gamma}) \end{bmatrix} \sim \mathcal{N}\left( \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}, \begin{bmatrix} \sigma_e^2 \mathbf{I}_{3N_L} & \mathbf{0} \\ \mathbf{0} & \sigma_e^2 \mathbf{I}_{3N_L} \end{bmatrix} \right)$$
(14)

where  $\mathbf{v}_d(\mathbf{\Gamma})$  and  $\mathbf{v}_{od}(\mathbf{\Gamma})$  (both  $\mathbb{R}^{3N_L \times 3} \to \mathbb{R}^{3N_L \times 1}$ ) denote the vectorization operators to stack the diagonal (i.e.,  $\boldsymbol{\gamma}_{j,j}$  for  $j \in \{1, 2, 3\}$ ) and the off-diagonal (i.e.,  $\boldsymbol{\gamma}_{j,k}$  for  $j \neq k$  and  $j, k \in \{1, 2, 3\}$ ) columns of any matrix  $\mathbf{\Gamma} \in \mathbb{R}^{3N_L \times 3}$  having the structure in (8).

**Remark 2:** The use of the Gaussian error model in (14), which is also employed in [21]–[23], [30], can be justified by the fact that the Gaussian distribution corresponds to the worst-case scenario as it maximizes the differential entropy for a given mean and variance. Hence, it leads to a conservative (robust) approach.

**Remark 3:** Referring to Remark 1, the transmitter related parameters,  $l_t^i$ ,  $n_t^i$ ,  $m_i$ ,  $E_1^i$ ,  $E_2^i$ , and  $E_3^i$ , are already available at the central controller, and the receiver related parameters,  $R_p$ , S,  $\sigma^2$ , and  $n_r$ , can be sent to the central controller via the uplink (e.g., via WiFi or infrared links [17], [19]). In addition, the position estimate at the VLC receiver can be sent to the central controller regularly so that it can have imperfect knowledge of  $l_r$  for the power allocation operation in the next cycle. Overall, the uncertainty in the knowledge of  $\Gamma$  is caused by many factors such as the errors in measuring parameters, the errors during communications from the VLC receiver.

As the Gaussian distributed errors  $\Delta\Gamma_{jk}$  are unbounded, a worst-case constraint on the CRLB cannot be imposed. Therefore, in order to handle such uncertainties, we propose a *chance constrained programming* based optimization approach, where we introduce an upper constraint  $\zeta$  on the probability that the CRLB exceeds a certain level  $\epsilon$ . This constraint can be stated as

$$\operatorname{Prob}_{\Delta\Gamma}\left\{\operatorname{trace}\left\{\mathbf{J}^{-1}(\mathbf{p})\right\} \le \epsilon\right\} \ge 1 - \zeta \tag{15}$$

where  $\Delta\Gamma$  has the distribution specified in (14) and  $\epsilon$  represents the threshold value that the CRLB is expected to exceed only by a maximum chance of  $\zeta \in (0, 1)$ , which is called the *localization accuracy outage probability*. (For notational simplicity, we omit subscript  $\Delta\Gamma$  in (15) in the remainder of the manuscript.) The minimum total power consumption problem with the localization accuracy outage probability constraint can then be proposed as

$$\underset{\mathbf{p}}{\text{ninimize}} \quad \mathbf{1}^T \mathbf{p} \tag{16a}$$

subject to  $\operatorname{Prob}\left\{\operatorname{trace}\left\{\mathbf{J}^{-1}(\mathbf{p})\right\} \le \epsilon\right\} \ge 1 - \zeta$  (16b)

$$\mathbf{p} \in \mathcal{P}$$
 (16c)

where  $\mathbf{J}(\mathbf{p}) = (\mathbf{I}_3 \otimes \mathbf{p})^T (\widetilde{\mathbf{\Gamma}} - \mathbf{\Delta}\mathbf{\Gamma})$  is the FIM given in (7) and  $\mathcal{P} \triangleq \mathcal{P}_1 \cap \mathcal{P}_3 \cap \mathcal{P}_4$  stands for the practical LED power constraints mentioned in Sec. III-B (please see (10), (11), and (13)).

Since the chance constraint in (16b) is not computationally tractable, we resort to the *sphere bounding* method to derive a tractable convex constraint that provides a safe approximation to (16b) in the sense that any point satisfying the new constraint also satisfies (16b) [33]. The following proposition presents a worst-case type deterministic condition under which the probabilistic constraint (16b) always holds.

**Proposition 1.** Let  $\mathcal{B} \triangleq \{\Psi \in \mathbb{R}^{3N_L \times 3} : ||\Psi|| \le \xi\}$ , where  $|| \cdot ||$  denotes the matrix spectral norm and  $\xi$  is defined as

$$\xi \triangleq \sigma_e \sqrt{3\Phi_{\chi^2_{3N_L}}^{-1} \left(\sqrt{1-\zeta}\right)} \tag{17}$$

with  $\Phi_{\chi^2_{3N_L}}^{-1}(\cdot)$  denoting the inverse cumulative distribution function (CDF) of a chi-squared random variable with  $3N_L$  degrees of freedom. Then, the following implication holds true:

trace{
$$[(\mathbf{I}_{3} \otimes \mathbf{p})^{T} (\widetilde{\mathbf{\Gamma}} - \mathbf{\Psi})]^{-1}$$
}  $\leq \epsilon, \forall \mathbf{\Psi} \in \mathcal{B} \implies$   
Prob {trace{ $[(\mathbf{I}_{3} \otimes \mathbf{p})^{T} (\widetilde{\mathbf{\Gamma}} - \mathbf{\Delta}\mathbf{\Gamma})]^{-1}$ }  $\leq \epsilon$ }  $\geq 1 - \zeta.$  (18)

*Proof.* We define new sets  $\mathcal{B}_s$  and  $\widetilde{\mathcal{B}}$  as

$$\mathcal{B}_{s} \triangleq \left\{ \boldsymbol{\Psi} \in \mathbb{R}^{3N_{L} \times 3} : ||\mathbf{v}_{d}(\boldsymbol{\Psi})||_{2} \leq \frac{\xi}{\sqrt{3}}, \\ ||\mathbf{v}_{od}(\boldsymbol{\Psi})||_{2} \leq \frac{\xi}{\sqrt{3}} \right\}$$
(19)

and

$$\widetilde{\mathcal{B}} \triangleq \{ \Psi \in \mathbb{R}^{3N_L \times 3} : ||\Psi||_F \le \xi \}$$
(20)

where  $|| \cdot ||_F$  denotes the Frobenius norm. First, we note that

$$\operatorname{Prob}\left\{\boldsymbol{\Delta\Gamma}\in\mathcal{B}_{s}\right\}$$

$$=\operatorname{Prob}\left\{||\mathbf{v}_{d}(\boldsymbol{\Delta\Gamma})||_{2}\leq\frac{\xi}{\sqrt{3}}\right\}\operatorname{Prob}\left\{||\mathbf{v}_{od}(\boldsymbol{\Delta\Gamma})||_{2}\leq\frac{\xi}{\sqrt{3}}\right\}$$

$$=\left[\operatorname{Prob}\left\{(||\mathbf{v}_{d}(\boldsymbol{\Delta\Gamma})||_{2}/\sigma_{e})^{2}\leq\Phi_{\chi_{3N_{L}}^{2}}^{-1}\left(\sqrt{1-\zeta}\right)\right\}\right]^{2}$$

$$(21b)$$

$$(21c)$$

$$= 1 - \zeta \tag{21c}$$

where (21a) follows from (19) and (14), (21b) is based on (17), and (21c) is due to (14) and the definition of  $\Phi_{\chi^2_{3N_L}}^{-1}(\cdot)$ . Now, assume that the left-hand-side (LHS) of (18) is satisfied. Since  $\mathcal{B}_s \subseteq \widetilde{\mathcal{B}}$  via (19) and (20), and  $\widetilde{\mathcal{B}} \subseteq \mathcal{B}$  via  $||\Psi|| \leq ||\Psi||_F$ , we obtain

trace{
$$[(\mathbf{I}_3 \otimes \mathbf{p})^T (\widetilde{\mathbf{\Gamma}} - \boldsymbol{\Psi})]^{-1}$$
}  $\leq \epsilon, \ \forall \boldsymbol{\Psi} \in \mathcal{B}_s.$  (22)

<sup>&</sup>lt;sup>2</sup>It is noted that  $\Gamma$  in (8) contains  $6N_L$  free entries as  $\gamma_{k_1,k_2} = \gamma_{k_2,k_1}$ .

Then, we have

$$\operatorname{Prob}\left\{\operatorname{trace}\left\{\left[\left(\mathbf{I}_{3}\otimes\mathbf{p}\right)^{T}(\widetilde{\boldsymbol{\Gamma}}-\boldsymbol{\Delta}\boldsymbol{\Gamma})\right]^{-1}\right\}\leq\epsilon\right\}\\\geq\operatorname{Prob}\left\{\boldsymbol{\Delta}\boldsymbol{\Gamma}\in\mathcal{B}_{s}\right\}\quad(23)$$

which yields the desired result in (18) via (21).

Based on the implication in (18), the constraint (16b) can be replaced by the LHS of (18), which can be transformed into a set of linear matrix inequality (LMI) constraints. Proposition 2 asserts to construct a convex optimization problem that constitutes a conservative tractable approximation of the original problem in (16).

**Proposition 2.** *The chance constrained problem in* (16) *can safely be approximated through the following convex optimization problem (i.e., any feasible point of (24) is feasible for* (16)):

$$\underset{\mathbf{p},\mathbf{H},s,\mu}{\text{minimize}} \quad \mathbf{1}^T \mathbf{p}$$
 (24a)

subject to  $\operatorname{trace}{\mathbf{H}} \le \epsilon - Ds$  (24b)

$$\mathbf{\Phi}(\mathbf{p}, \mathbf{H}, s, \mu) \succeq 0, \mathbf{H} \succeq 0, \mu \ge 0 \qquad (24c)$$

$$\mathbf{p} \in \mathcal{P}$$
 (24d)

where D stands for the dimension of localization, H, s, and  $\mu$  are auxiliary variables, and

$$\Phi(\mathbf{p}, \mathbf{H}, s, \mu) \triangleq \begin{bmatrix} \mathbf{H} + s\mathbf{I} & \mathbf{I} & \mathbf{0} \\ \mathbf{I} & (\mathbf{I}_3 \otimes \mathbf{p})^T \widetilde{\mathbf{\Gamma}} - \mu \mathbf{I} & -\frac{\xi}{2} (\mathbf{I}_3 \otimes \mathbf{p})^T \\ \mathbf{0} & -\frac{\xi}{2} (\mathbf{I}_3 \otimes \mathbf{p}) & \mu \mathbf{I} \end{bmatrix}, \quad (25)$$

with  $\xi$  being defined in (17).

*Proof.* Following the same steps as in the proof of [20, Prop. 3], the LHS of (18) can be shown to be equivalent to the LMI constraints in (24b)-(24d). Hence, according to Proposition 1, the feasible region of (24) is contained entirely in the feasible region of (16).

Based on Proposition 2, the convex optimization problem in (24) can be solved to perform power efficient localization in VLP systems by satisfying the chance constraint in (16b) as well as the practical constraints in (16c).

#### **IV. NUMERICAL RESULTS**

In this section, we present a numerical example to investigate the performance of the proposed approach for the chance constrained minimum total power consumption problem. We consider an asynchronous VLP setup in a room of size  $10 \times 10 \times 5 \text{ m}^3$  with  $N_L = 4$  LED transmitters and a VLC receiver whose locations and orientations are as specified in [20, Table I]. The scaled version of the signal transmitted from the *i*th LED transmitter is modeled as  $\tilde{s}_i(t) = \frac{2}{3}(1 - \cos(2\pi t/T_{s,i}))(1 + \cos(2\pi f_{c,i}t))$  for  $i = 1, \ldots, N_L$  and  $t \in [0, T_{s,i}]$ , where the pulse width  $T_{s,i}$  and the center frequency  $f_{c,i}$  along with the other simulation parameters are as provided in [20, Table II]. The robust strategy illustrated in Fig. 1 refers to the solution of the convex approximation in (24). This strategy is compared with the non-robust strategy

$$\underset{\mathbf{p}}{\operatorname{minimize}} \quad \mathbf{1}^{T}\mathbf{p} \tag{26a}$$

of solving the worst-case accuracy constrained optimization problem using the noisy measurement  $\widetilde{\Gamma}$ , which can be for-

subject to  $\operatorname{trace}\{[(\mathbf{I}_3 \otimes \mathbf{p})^T \widetilde{\mathbf{\Gamma}}]^{-1}\} \le \epsilon$  (26b)

$$\mathbf{p} \in \mathcal{P}$$
 (26c)

and also with the uniform power allocation strategy of

$$P_i = \operatorname{trace}\{[(\mathbf{I}_3 \otimes \mathbf{1})^T \widetilde{\boldsymbol{\Gamma}}]^{-1}\}/\epsilon$$
(27)

for  $i \in \{1, ..., N_L\}$ .

mulated as [20]

Figs. 1(a) and 1(b) show the CDF of the CRLB for different noise variances in (14), namely,  $\sigma_e^2 = 10^{-4}$  and  $\sigma_e^2 = 4 \times 10^{-4}$ , respectively, where the outage probability limit in (16) is set to  $\zeta = 0.15$ . We observe that the proposed robust strategy satisfies the probabilistic constraint in (16), i.e., it guarantees the specified accuracy level  $\epsilon$  for  $100(1-\zeta)\%$  of the realizations. On the other hand, the other two approaches fail to satisfy the chance constraint in (16) as they disregard the probabilistic uncertainty in  $\Gamma$ . In addition, the robust strategy tends to over-satisfy the probabilistic constraint as  $\sigma_e$  decreases, which indicates that the approximation in Proposition 2 becomes tighter for higher levels of uncertainty.

Fig. 2 illustrates the average power of the LEDs versus the accuracy constraint  $\sqrt{\epsilon}$  for the robust, non-robust and uniform power allocation strategies, where  $\zeta = 0.15$  and  $\sigma_e^2 = 10^{-4}$ . It is observed that the uniform power allocation strategy consumes the highest transmit powers. Also, it is noted that the relative performance gain of the proposed robust strategy is achieved at the cost of higher transmit powers than those in the non-robust approach. However, it should be emphasized that the robust strategy provides a solid theoretical guarantee for satisfying the chance constraint in (16) unlike the non-robust and uniform power allocation approaches.

#### V. CONCLUDING REMARKS

In this work, the minimization of total power consumption in LED transmitters in a VLP system has been considered via a chance constrained programming approach. We have formulated the problem with a stochastic uncertainty model for the localization parameters. This yields an optimization problem having an intractable non-convex constraint related to the probability that the localization CRLB exceeds a certain level as well as constraints on LED powers regarding the hardware requirements and the illumination task of the VLP system. We have demonstrated that the sphere bounding method can be applied to approximate the non-convex constraint with a convex one, which facilitates the solution of the minimum total power consumption problem via standard convex optimization tools. The numerical results show that via the proposed robust approach, constraints on the localization accuracy outage probability can always be satisfied as opposed to the uniform and non-robust strategies, with a power consumption level in between the two.

**Onurcan Yazar** was born in 1997 in Antalya, Turkey. He received the B.S. degree from the Department of Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey, in 2019. He is currently pursuing the M.S. degree in the same department. His current research interests include wireless communications, visible light communications, and localization.

**Musa Furkan Keskin** is a postdoctoral researcher at Chalmers University of Technology. He obtained the B.S., M.S., and Ph.D degrees from the Department of Electrical and Electronics Engineering, Bilkent University, Ankara, Turkey, in 2010, 2012, and 2018, respectively. His current research interests include intelligent transportation systems, joint radar-communications and 5G positioning.

Sinan Gezici (S'03–M'06–SM'11) received the B.S. degree from Bilkent University, Turkey in 2001, and the Ph.D. degree in Electrical Engineering from Princeton University in 2006. From 2006 to 2007, he worked at Mitsubishi Electric Research Laboratories, Cambridge, MA. Since 2007, he has been with the Department of Electrical and Electronics Engineering at Bilkent University, where he is currently a Professor. Dr. Gezici's research interests are in the areas of detection and estimation theory, wireless communications, and localization systems.

Among his publications in these areas is the book Ultra-wideband Positioning Systems: Theoretical Limits, Ranging Algorithms, and Protocols (Cambridge University Press, 2008). Dr. Gezici was an associate editor for IEEE Transactions on Communications, IEEE Wireless Communications Letters, and Journal of Communications and Networks.

Fig. 1: CDF of localization CRLBs achieved by robust, non-robust, and uniform strategies in case of stochastic uncertainty, where the accuracy constraint on CRLB in (16) is set to  $\sqrt{\epsilon} = 0.06$  m, the outage probability constraint is  $\zeta = 0.15$ , and two different noise variances, (a)  $\sigma_e^2 = 10^{-4}$  and (b)  $\sigma_e^2 = 4 \times 10^{-4}$ , are considered.

Fig. 2: Optimal value of (16a) divided by  $N_L \left(P_{\rm avg}^*\right)$  versus accuracy constraint  $\sqrt{\epsilon}$  for robust, non-robust and uniform power allocation strategies, where the outage constraint is  $\zeta = 0.15$  and the noise variance is  $\sigma_e^2 = 10^{-4}$ .
