

Power Allocation for LED Arrays in Asynchronous Visible Light Positioning Systems

RAMAZAN YAZ 
SINAN GEZICI 

Bilkent University, Ankara, Türkiye

In this article, we develop power allocation strategies for asynchronous visible light positioning systems employing light-emitting diode arrays with the aim of improving localization accuracy. We formulate an optimization problem for minimizing the Cramér–Rao lower bound (CRLB) related to the estimation of the receiver location subject to practical constraints on total and individual transmission powers and required illumination levels. Due to the nonconvexity of the proposed formulation, we devise a two-step methodology. First, a convex optimization problem is employed to determine the power allocation that maximizes the total received power. Subsequently, a projected gradient descent algorithm is utilized to refine the power allocation according to the CRLB metric under the power and illumination constraints. In addition, a framework for iterative power allocation and localization is developed for practical deployment, in which each step of the optimization process uses the most recent position estimate. Simulation results indicate that the proposed method can outperform both the uniform and power-maximization-based allocation schemes, resulting in improved localization accuracy over a wide range of operating conditions. Hence, it can provide robust and high-precision indoor positioning, even in circumstances involving asynchronous transmission and stringent illumination requirements.

I. INTRODUCTION

Visible light positioning (VLP) has gained considerable attention as a promising alternative to radio-frequency (RF)-based localization, particularly in indoor environments [1], [2]. Leveraging light-emitting diodes (LEDs) as both illumination sources and positioning anchors, VLP systems provide precise localization by utilizing received optical signals from LED transmitters at known locations [3]. Unlike RF-based positioning, VLP benefits from unlicensed spectrum, reduced interference, and specific line-of-sight (LOS) properties of visible light, making it a suitable choice for applications in smart environments, industrial automation, and intelligent transportation systems [4], [5].

For a given VLP system, theoretical limits on position estimation accuracy and optimal estimators that (asymptotically) achieve those limits have been studied in numerous studies in the literature such as [6], [7], [8], [9], [10], [11], [12], [13], [14], and [15]. In [6], both received signal strength (RSS) and angle-of-arrival (AOA) measurements are employed within a visible light communication (VLC) system with multiple LED transmitters and a single receiver for 3-D localization. The study also derives the Cramér–Rao lower bound (CRLB) based on RSS, specifying 3-D positioning performance across various deployment scenarios. Similarly, RSS and AOA are utilized in a 3-D indoor positioning method involving a single LED array and multiple VLC receivers in [7]. Two-dimensional VLP based on RSS is explored in [10] and [11], assuming a fixed receiver height. This setup employs an aperture-based receiver, and the CRLB is derived to assess the effectiveness of the proposed positioning algorithms. Moreover, Zhou et al. [12] analyze the influence of non-line-of-sight (NLOS) components, signal-to-noise ratio (SNR), transmission distance, and the number of LED sources on the performance of RSS-based VLP systems, providing closed-form CRLB expressions for both position and orientation estimation. In [14], CRLBs and maximum likelihood (ML) estimators are derived for both synchronous and asynchronous VLP networks considering direct and two-step positioning approaches. It is shown that the two-step approach is equivalent to the direct ML estimator for asynchronous VLP systems. In addition, Shen et al. [15] investigate joint position and orientation estimation in RSS-based VLP systems using multiple LED transmitters and multiple VLC receivers.

Once optimal estimators are designed for VLP systems as in [14] and [15], further improvements on localization accuracy can be achieved by optimizing the parameters of LED transmitters. In particular, a key challenge in VLP systems is to optimize the transmission parameters of LEDs to enhance localization accuracy while considering practical system constraints such as power limitations and illumination requirements. Previous research has focused on power allocation strategies for LED transmitters to minimize localization errors by optimizing the CRLB, thereby improving positioning performance under various uncertainty models [16], [17], [18], [19], [20], [21], [22].

Specifically, Keskin et al. [17] propose an optimal and robust power allocation framework for LED transmitters to minimize the localization error of VLC receivers while satisfying practical power and illumination constraints. This approach demonstrates significant improvements over uniform power allocation strategies by leveraging convex optimization and robust design principles. In [19], a robust power allocation scheme is introduced that jointly optimizes positioning accuracy and data throughput under random positioning errors. By formulating a chance-constrained optimization problem and deriving explicit relationships between positioning and channel state information uncertainties, the authors transform these probabilistic constraints into convex forms. The proposed approach yields superior localization performance and communication reliability in comparison with the conventional uniform or nonrobust allocation strategies. On the other hand, Yazar et al. [20] introduce a power-efficient positioning framework for VLC networks by formulating a chance-constrained optimization problem to minimize the total transmit power of LED arrays while guaranteeing that the CRLB on localization errors remains below a desired threshold with high probability. This approach accounts for stochastic uncertainties in system parameters by imposing probabilistic (rather than deterministic) constraints on localization accuracy and enables robust performance improvements over both nonrobust methods and uniform power allocation strategies. On the other hand, resource allocation strategies based on CRLB minimization have also been studied in the context of radar [23], [24]. However, the design of power allocation strategies for VLP systems involves unique challenges and constraints that distinguish it from radar-based approaches. First of all, the channel characteristics differ fundamentally as VLP systems operate over optical channels modeled by Lambertian radiation patterns unlike radar systems. Moreover, VLP systems simultaneously perform positioning and illumination in indoor environments, subjecting them to illumination constraints, which differentiates them from RF systems. Overall, the CRLB optimization under illumination and power constraints leads to a different problem from those in the RF localization literature.

Although power allocation problems have been investigated for VLP systems in the literature such as [17], [19], and [22], there exist no studies that investigate optimal power allocation for *LED arrays* in asynchronous VLP systems for minimizing the CRLB under power and illumination constraints. In this manuscript, we develop a new power allocation technique for LED arrays in asynchronous VLP systems, which effectively performs spatial beamforming for improving localization accuracy by jointly optimizing the power distribution among multiple LEDs within each array. After formulating the proposed problem of power allocation for LED arrays under practical power and illumination constraints, we solve it in two steps. We first find an initial solution, which is obtained by solving a convex problem corresponding to received power maximization. Then, we employ a projected gradient descent algorithm starting from that initial solution by utilizing an explicit expression

for the gradient term. In addition, we develop an iterative version of the algorithm for practical scenarios where power allocation and localization are performed iteratively.

The main contributions and novelty of this manuscript are summarized as follows.

- 1) We propose a power allocation (effectively, beam-forming) approach for LED arrays in an asynchronous VLP system to minimize the CRLB on position estimation under practical power and illumination constraints.
- 2) We derive a CRLB expression for position estimation in terms of transmit power parameters of LED arrays, which is a nonconvex function in general (unlike the convex CRLB expression in [17] derived for transmitters with single LEDs).
- 3) To obtain a solution of the nonconvex problem of power allocation, we first focus on the problem of received power maximization, which results in a convex problem and provides an initial point for the proposed nonconvex optimization problem. Then, we explicitly calculate the gradient of the CRLB and minimize it under the power and illumination constraints via projected gradient descent.
- 4) For practical deployments, we propose an iterative approach of power allocation and localization, where the VLC receiver performs ML-based localization and the power allocation is performed based on the ML estimates.

Via simulation results, we demonstrate the effectiveness of our proposed power allocation strategy in improving localization performance compared to the conventional uniform power allocation and received power maximization techniques.

II. SYSTEM MODEL

We focus on a VLP system with N LED arrays, where the i th LED array consist of L_i LEDs for $i = 1, \dots, N$. The location and the orientation vector of the j th LED in the i th LED array are denoted by $\mathbf{l}_{i,j}$ and $\mathbf{n}_{i,j}$, respectively, which are assumed to be known for all $j \in \{1, \dots, L_i\}$ and $i \in \{1, \dots, N\}$. We consider the localization of a generic VLC receiver at an unknown location denoted by $\mathbf{x}$, and assume that the VLC receiver knows its orientation vector denoted by $\bar{\mathbf{n}}$, which can be determined, for example, via a gyroscope [17], [25].

Considering an asynchronous VLP system, in which the VLC receiver is not synchronized with the LED arrays [14], the aim is for the VLC receiver to estimate its unknown location $\mathbf{x}$ based on power measurements of incoming signals emitted by the LED arrays. We propose a system in which the LEDs in each LED array transmit the scaled version of a base signal simultaneously during each localization interval. More specifically

$$s_{i,j}(t) = \sqrt{w_{i,j}} \tilde{s}_i(t) \quad (1)$$

Fig. 1. Block diagram of the i th LED array in the considered VLP system, where $i \in \{1, \dots, N\}$.

represents the transmitted optical signal from the j th LED in the i th LED array, where $w_{i,j} \geq 0$ is the transmit power parameter and $\tilde{s}_i(t)$ denotes a base signal for the i th LED array, which satisfies $\int_0^{T_{s,i}} \tilde{s}_i^2(t) dt / T_{s,i} = 1$ with $[0, T_{s,i}]$ representing the interval for the support of $\tilde{s}_i$ for $i = 1, \dots, N$. The block diagram for an LED array is shown in Fig. 1.

Assuming a certain type of multiplexing approach, e.g., frequency or code division multiplexing, the VLC receiver observes the signals coming from the LED arrays separately [26], [27]. Also, as in [8], [14], [15], [28], and [29], only the LOS signals between the LEDs and the VLC receiver are considered.¹ Accordingly, the signal received at the VLC receiver due to the signals from the i th LED array can be modeled as follows:

$$r_i(t) = R_p \sum_{j=1}^{L_i} h_{i,j} \sqrt{w_{i,j}} \tilde{s}_i(t - \tau_{i,j}) + \tilde{\eta}_i(t) \quad (2)$$

for $i \in \{1, \dots, N\}$ and $t \in [T_{1,i}, T_{2,i}]$, where $T_{1,i}$ and $T_{2,i}$ specify the observation interval for the signal coming from the i th LED array, R_p is the responsivity of the photodetector at the VLC receiver, $h_{i,j}$ is the channel gain of the signal between the j th LED in the i th LED array and the VLC receiver, $\tau_{i,j}$ is the time-of-arrival of the signal emitted by j th LED in the i th LED array, and $\tilde{\eta}_i(t)$ is zero-mean white Gaussian noise with a spectral density level of σ^2 .

Considering practical indoor environments and LED array sizes, the duration of the optical signals in (1) is commonly much longer than the differences among the TOA's of the incoming signals from a given LED array; namely, among $\tau_{i,1}, \dots, \tau_{i,L_i}$. Therefore, $\tilde{s}_i(t - \tau_{i,j}) \approx \tilde{s}_i(t - \tau_i)$ for $j = 1, \dots, L_i$ for each $i \in \{1, \dots, N\}$, where τ_i can be set

to one of $\tau_{i,1}, \dots, \tau_{i,L_i}$. Accordingly, (2) can be stated as

$$r_i(t) = R_p \left(\sum_{j=1}^{L_i} h_{i,j} \sqrt{w_{i,j}} \right) \tilde{s}_i(t - \tau_i) + \tilde{\eta}_i(t). \quad (3)$$

Since τ_i 's are unknown in asynchronous VLP systems, the power of the received signal in (3) can be obtained by correlating it with $\tilde{s}_i(t - \tau)$ for all possible τ values and determining the peak value, as described in [14]. Consequently, the received power measurement at the VLC receiver due to the signal from the i th LED array can be modeled as follows (after some normalization to remove the constant terms for simplifying the notation) [9], [25], [30], [31]:

$$P_{RX,i} = \sum_{j=1}^{L_i} h_{i,j} \sqrt{w_{i,j}} + \eta_i, \quad i = 1, \dots, N \quad (4)$$

where η_i is a zero-mean Gaussian noise component with a variance of σ_i^2 , which is independent of η_j for all $j \neq i$ [31].

The channel gain $h_{i,j}$ in (4) can be expressed as

$$h_{i,j} = \frac{(m_{i,j} + 1)A (\cos \phi_{i,j})^{m_{i,j}} T_s(\psi_{i,j}) g(\psi_{i,j}) \cos \psi_{i,j}}{2\pi \|\mathbf{x} - \mathbf{l}_{i,j}\|^2} \quad (5)$$

where $m_{i,j}$ is the Lambertian order for the j th LED in the i th LED array, A is the area of the photodetector at the VLC receiver, $\phi_{i,j}$ and $\psi_{i,j}$ are, respectively, the irradiance angle and the incidence angle for the LOS path between the j th LED in the i th LED array and the VLC receiver, and $T_s(\psi)$ and $g(\psi)$ are, respectively, the optical filter gain and the optical concentrator gain at the VLC receiver [30]. It is common to have a design with $T_s(\psi)g(\psi)$ being a constant [30]; hence, it can be set to unity to simplify the notation. Although the preceding expressions are presented as if all the LEDs are in the field-of-view (FOV) of the photodetector at the VLC receiver, these formulations can still be used if some LEDs are not in the FOV of the photodetector by excluding those LEDs from the CRLB expressions in Section III-A. (Commonly, the LED transmitters are at the ceiling of a room, and the VLC receiver is close to the floor level pointing upwards and having an FOV of 90° by using a hemispherical lens [32], [33]. Hence, most of the LEDs are in the FOV of the VLC receiver in practical applications.)

By calculating the angles in (5) based on the geometric relations of $(\mathbf{x} - \mathbf{l}_{i,j})^T \mathbf{n}_{i,j} = \|\mathbf{x} - \mathbf{l}_{i,j}\| \cos \phi_{i,j}$ and $(\mathbf{l}_{i,j} - \mathbf{x})^T \mathbf{\bar{n}} = \|\mathbf{l}_{i,j} - \mathbf{x}\| \cos \psi_{i,j}$, the channel gain in (5) can be expressed as follows:

$$h_{i,j} = \frac{(m_{i,j} + 1)A ((\mathbf{x} - \mathbf{l}_{i,j})^T \mathbf{n}_{i,j})^{m_{i,j}} (\mathbf{l}_{i,j} - \mathbf{x})^T \mathbf{\bar{n}}}{2\pi \|\mathbf{x} - \mathbf{l}_{i,j}\|^{m_{i,j}+3}}. \quad (6)$$

III. POWER ALLOCATION FOR LED ARRAYS

By adjusting the transmit power parameters $w_{i,j}$ in (4), the LED arrays can effectively form beams in specific directions. The aim is to design these power parameters

¹It is noted that although multipath reflections exist in practical indoor environments, the LOS component is typically dominant in VLP systems [7], [8]. Furthermore, incorporating complex multipath channel models would render the derivation of closed-form CRLB expressions and the subsequent nonconvex optimization framework computationally intractable. Therefore, consistent with the theoretical VLP literature, this work focuses on the LOS regime. The investigation of multipath effects and hardware imperfections are left as a future research direction.

of the LEDs in each LED array for enhancing the localization accuracy. Since the design for a specific position estimator would not be practical, we consider a theoretical performance metric based on the Fisher information matrix (FIM) related to estimating the position of the VLC receiver. Such approaches have been used in the literature extensively due to their practicality, generality, and asymptotic relation to ML estimation [34]. In this manuscript, we consider the minimization of the trace of the inverse FIM, i.e., CRLB, which provides a lower limit on mean squared errors (MSEs) of unbiased estimators. It is known that the MSE of the ML estimator converges to the CRLB in the high SNR regime [35].

A. Derivation of CRLB

To derive the CRLB for the proposed setting, we first consider the received power model given in (4) and obtain the log-likelihood function for the unknown position $\mathbf{x}$ based on the received power vector $\mathbf{P}_{\text{RX}} = [P_{\text{RX},1} \dots P_{\text{RX},N}]^T$ (i.e., the logarithm of the conditional probability density function of $\mathbf{P}_{\text{RX}}$ given $\mathbf{x}$) as [35]

$$\Lambda(\mathbf{x}) = \tilde{k} - \sum_{i=1}^N \frac{1}{2\sigma_i^2} \left(P_{\text{RX},i} - \sum_{j=1}^{L_i} h_{i,j} \sqrt{w_{i,j}} \right)^2 \quad (7)$$

where $\tilde{k}$ is a normalizing constant that does not depend on the unknown parameter vector $\mathbf{x}$.

The CRLB on the variance of any unbiased estimator $\hat{\mathbf{x}}$ for the location of the VLC receiver $\mathbf{x}$ can be expressed as [35]

$$\mathbb{E} \{ \|\hat{\mathbf{x}} - \mathbf{x}\|^2 \} \leq \text{trace} \{ \mathbf{J}^{-1}(\mathbf{x}) \} \quad (8)$$

where $\mathbf{J}(\mathbf{x})$ is the FIM for $\mathbf{x}$, which is defined as

$$\mathbf{J}(\mathbf{x}) = \mathbb{E} \{ (\nabla_{\mathbf{x}} \Lambda(\mathbf{x})) (\nabla_{\mathbf{x}} \Lambda(\mathbf{x}))^T \}. \quad (9)$$

Here, $\nabla_{\mathbf{x}} \Lambda(\mathbf{x})$ represents the gradient of $\Lambda(\mathbf{x})$ in (7) with respect to $\mathbf{x} = [x_1 \ x_2 \ x_3]^T$. The elements of the FIM in (9) can be expressed as

$$[\mathbf{J}(\mathbf{x})]_{k_1, k_2} = \mathbb{E} \left\{ \frac{\partial \Lambda(\mathbf{x})}{\partial x_{k_1}} \frac{\partial \Lambda(\mathbf{x})}{\partial x_{k_2}} \right\} \quad (10)$$

for $k_1, k_2 \in \{1, 2, 3\}$, which can be calculated based on (7) as follows:

$$[\mathbf{J}(\mathbf{x})]_{k_1, k_2} = \sum_{i=1}^N \frac{1}{\sigma_i^2} \left(\sum_{j=1}^{L_i} \sqrt{w_{i,j}} \frac{\partial h_{i,j}}{\partial x_{k_1}} \right) \left(\sum_{j=1}^{L_i} \sqrt{w_{i,j}} \frac{\partial h_{i,j}}{\partial x_{k_2}} \right). \quad (11)$$

In (11), the partial derivatives are given by [25]

$$\begin{aligned} \frac{\partial h_{i,j}}{\partial x_k} = & \frac{-(m_{i,j} + 1)A}{2\pi \|\mathbf{x} - \mathbf{l}_{i,j}\|^{m_{i,j}+3}} \left[\tilde{n}_k ((\mathbf{x} - \mathbf{l}_{i,j})^T \mathbf{n}_{i,j})^{m_{i,j}} \right. \\ & - m_{i,j} n_{i,j,k} ((\mathbf{x} - \mathbf{l}_{i,j})^T \mathbf{n}_{i,j})^{m_{i,j}-1} (\mathbf{l}_{i,j} - \mathbf{x})^T \tilde{\mathbf{n}} \\ & \left. + \frac{(m_{i,j} + 3)(x_k - l_{i,j,k}) ((\mathbf{x} - \mathbf{l}_{i,j})^T \mathbf{n}_{i,j})^{m_{i,j}} (\mathbf{l}_{i,j} - \mathbf{x})^T \tilde{\mathbf{n}}}{\|\mathbf{x} - \mathbf{l}_{i,j}\|^2} \right] \end{aligned} \quad (12)$$

where $\tilde{n}_k$, $n_{i,j,k}$, and $l_{i,j,k}$ denote the k th elements of $\tilde{\mathbf{n}}$, $\mathbf{n}_{i,j}$, and $\mathbf{l}_{i,j}$, respectively.

By defining $\sqrt{\mathbf{w}_i} \triangleq [\sqrt{w_{i,1}} \dots \sqrt{w_{i,L_i}}]^T$ as the vector of transmit power parameters for the i th LED array and $\mathbf{h}_i = [h_{i,1} \dots h_{i,L_i}]^T$ as the channel gain vector related to the LEDs in the i th LED array and the VLC receiver, we can state (11) as follows:

$$[\mathbf{J}(\mathbf{x})]_{k_1, k_2} = \sum_{i=1}^N \frac{1}{\sigma_i^2} \sqrt{\mathbf{w}_i}^T \left(\frac{\partial \mathbf{h}_i}{\partial x_{k_1}} \frac{\partial \mathbf{h}_i^T}{\partial x_{k_2}} \right) \sqrt{\mathbf{w}_i}. \quad (13)$$

The expression in (13) can be written as

$$[\mathbf{J}(\mathbf{x})]_{k_1, k_2} = \sum_{i=1}^N \sqrt{\mathbf{w}_i}^T \mathbf{H}_{k_1, k_2}^i \sqrt{\mathbf{w}_i} \quad (14)$$

where $\mathbf{H}_{k_1, k_2}^i \triangleq \frac{1}{\sigma_i^2} \left(\frac{\partial \mathbf{h}_i}{\partial x_{k_1}} \frac{\partial \mathbf{h}_i^T}{\partial x_{k_2}} \right)$. As a result, we can obtain the FIM as

$$\mathbf{J}(\mathbf{x}) = \begin{bmatrix} \sqrt{\mathbf{w}}^T \mathbf{H}_{1,1} \sqrt{\mathbf{w}} & \sqrt{\mathbf{w}}^T \mathbf{H}_{1,2} \sqrt{\mathbf{w}} & \sqrt{\mathbf{w}}^T \mathbf{H}_{1,3} \sqrt{\mathbf{w}} \\ \sqrt{\mathbf{w}}^T \mathbf{H}_{2,1} \sqrt{\mathbf{w}} & \sqrt{\mathbf{w}}^T \mathbf{H}_{2,2} \sqrt{\mathbf{w}} & \sqrt{\mathbf{w}}^T \mathbf{H}_{2,3} \sqrt{\mathbf{w}} \\ \sqrt{\mathbf{w}}^T \mathbf{H}_{3,1} \sqrt{\mathbf{w}} & \sqrt{\mathbf{w}}^T \mathbf{H}_{3,2} \sqrt{\mathbf{w}} & \sqrt{\mathbf{w}}^T \mathbf{H}_{3,3} \sqrt{\mathbf{w}} \end{bmatrix} \quad (15)$$

where $\sqrt{\mathbf{w}} \triangleq [\sqrt{w_1} \dots \sqrt{w_N}]^T$ and $\mathbf{H}_{k_1, k_2}$ is given by

$$\mathbf{H}_{k_1, k_2} = \text{blkdiag}(\mathbf{H}_{k_1, k_2}^1, \dots, \mathbf{H}_{k_1, k_2}^N). \quad (16)$$

That is, $\mathbf{H}_{k_1, k_2}$ is a block diagonal matrix whose blocks are $\mathbf{H}_{k_1, k_2}^i$ for $i = 1, \dots, N$.

The FIM given in (15) can be written in a compact form as

$$\mathbf{J}(\mathbf{x}) = (\mathbf{I}_3 \otimes \sqrt{\mathbf{w}})^T \mathbf{H} (\mathbf{I}_3 \otimes \sqrt{\mathbf{w}}) \quad (17)$$

where $\mathbf{I}_3$ is the 3×3 identity matrix, $\otimes$ represents the Kronecker product, and $\mathbf{H}$ is a block matrix whose blocks are the $\mathbf{H}_{k_1, k_2}$ matrices; i.e.,

$$\mathbf{H} = \begin{bmatrix} \mathbf{H}_{1,1} & \mathbf{H}_{1,2} & \mathbf{H}_{1,3} \\ \mathbf{H}_{2,1} & \mathbf{H}_{2,2} & \mathbf{H}_{2,3} \\ \mathbf{H}_{3,1} & \mathbf{H}_{3,2} & \mathbf{H}_{3,3} \end{bmatrix}. \quad (18)$$

The aim is to minimize the CRLB in (17) subject to practical power and illumination constraints, which are described next.

B. Power Constraints

For LEDs to operate in the linear region and to achieve efficient electrical to optical conversion, lower and upper limits can be imposed on the transmit powers [17]. Accordingly, the transmit power parameters are constrained as

$$w_{i,j}^{\text{low}} \leq w_{i,j} \leq w_{i,j}^{\text{upp}} \quad (19)$$

for all $j \in \{1, \dots, L_i\}$ and $i \in \{1, \dots, N\}$, where $w_{i,j}^{\text{low}}$ and $w_{i,j}^{\text{upp}}$ denote the lower and upper bounds, respectively. The constraints in (19) can also be expressed in the vector form as

$$\mathbf{w}^{\text{low}} \leq \mathbf{w} \leq \mathbf{w}^{\text{upp}} \quad (20)$$

by forming $\mathbf{w}^{\text{low}}$ and $\mathbf{w}^{\text{upp}}$ in the same manner as $\mathbf{w}$, which is defined as $\mathbf{w} \triangleq [\mathbf{w}_1^T \dots \mathbf{w}_N^T]^T$ with $\mathbf{w}_i \triangleq [w_{i,1} \dots w_{i,L_i}]^T$. In addition to the individual power constraints in (20), there also exist total power constraints related to power consumption and human eye safety considerations [17], which can be stated as

$$\sum_{j=1}^{L_i} w_{i,j} \leq w_i^{\text{tot}} \quad (21)$$

for $i = 1, \dots, N$. The total power constraints in (21) can be written in the vector form as

$$\mathbf{B}\mathbf{w} \leq \mathbf{w}^{\text{tot}} \quad (22)$$

where $\mathbf{w}^{\text{tot}} \triangleq [w_1^{\text{tot}} \dots w_N^{\text{tot}}]^T$ and

$$\mathbf{B} \triangleq \text{blkdiag}(\mathbf{1}_{L_1}^T, \dots, \mathbf{1}_{L_N}^T) \quad (23)$$

with $\mathbf{1}_{L_i}$ denoting a column vector of L_i ones.

C. Illumination Constraints

As visible light systems are commonly utilized for illumination purposes as well, individual and average illumination constraints should also be considered. The horizontal illuminance at location $\mathbf{y}$ produced by the j th LED in the i th LED array can be calculated as follows [17]:

$$\mathcal{I}_{\text{ind}}^{i,j}(\mathbf{y}, w_{i,j}) = \sqrt{w_{i,j}} \varphi_{i,j}(\mathbf{y}) \quad (24)$$

where

$$\begin{aligned} \varphi_{i,j}(\mathbf{y}) &= \frac{(m_{i,j} + 1)\kappa_{i,j}\tilde{E}_{i,j}^{\text{opt}}}{2\pi} \\ &\times \frac{((\mathbf{y} - \mathbf{l}_{i,j})^T \mathbf{n}_{i,j})^{m_{i,j}} (\mathbf{l}_{i,j}(3) - \mathbf{y}(3))}{\|\mathbf{y} - \mathbf{l}_{i,j}\|^{m_{i,j}+3}} \end{aligned} \quad (25)$$

with $\kappa_{i,j}$ representing the luminous efficacy (lm/W) of the j th LED in the i th LED array, $\tilde{E}_{i,j}^{\text{opt}}$ denoting the optical power of the base signal in (1), that is, $\tilde{E}_{i,j}^{\text{opt}} \triangleq \int_0^{T_{s,i}} \tilde{s}_{i,j}(t)dt / T_{s,i}$, and $\mathbf{l}_{i,j}(3)$ and $\mathbf{x}(3)$ being the third components of $\mathbf{l}_{i,j}$ and $\mathbf{x}$, respectively. Therefore, the total illuminance at $\mathbf{y}$ generated by all the LEDs can be calculated as

$$\mathcal{I}_{\text{ind}}(\mathbf{y}, \mathbf{w}) = \sum_{i=1}^N \sum_{j=1}^{L_i} \sqrt{w_{i,j}} \varphi_{i,j}(\mathbf{y}) = \sqrt{\mathbf{w}}^T \boldsymbol{\varphi}(\mathbf{y}) \quad (26)$$

where $\boldsymbol{\varphi}(\mathbf{y})$ represents the illuminance coefficient vector, defined as

$$\boldsymbol{\varphi}(\mathbf{y}) \triangleq [\varphi_{1,1}(\mathbf{y}) \dots \varphi_{1,L_1}(\mathbf{y}) \dots \varphi_{N,1}(\mathbf{y}) \dots \varphi_{N,L_N}(\mathbf{y})]^T. \quad (27)$$

If there exist M locations denoted by $\mathbf{y}_1, \dots, \mathbf{y}_M$ where illuminance constraints are to be satisfied, the following set of constraints can be stated:

$$\sqrt{\mathbf{w}}^T \boldsymbol{\varphi}(\mathbf{y}_\ell) \geq \tilde{\mathcal{I}}_\ell, \ell \in \{1, \dots, M\} \quad (28)$$

with $\tilde{\mathcal{I}}_\ell$ specifying the illuminance constraint for location $\mathbf{y}_\ell$.

In addition to the individual illumination constraints in (28), there can also exist an average illumination constraint over a region in the positioning environment. The average illuminance can be specified as follows [17]:

$$\mathcal{I}_{\text{avg}}(\mathbf{w}) = \sum_{i=1}^N \sum_{j=1}^{L_i} \sqrt{w_{i,j}} \frac{\int_{\mathcal{R}} \varphi_{i,j}(\mathbf{y}) d\mathbf{y}}{|\mathcal{R}|} \quad (29)$$

where $\mathcal{R}$ denotes the region over which the average illuminance constraint must be satisfied, and $|\mathcal{R}|$ represents its volume. Then, the average illuminance constraint can be stated as

$$\sqrt{\mathbf{w}}^T \bar{\boldsymbol{\varphi}}_{\mathcal{R}} \geq \tilde{\mathcal{I}}_{\text{avg}} \quad (30)$$

where $\bar{\boldsymbol{\varphi}}_{\mathcal{R}} \triangleq |\mathcal{R}|^{-1} [\int_{\mathcal{R}} \varphi_{1,1}(\mathbf{y}) d\mathbf{y} \dots \int_{\mathcal{R}} \varphi_{1,L_1}(\mathbf{y}) d\mathbf{y} \dots \int_{\mathcal{R}} \varphi_{N,1}(\mathbf{y}) d\mathbf{y} \dots \int_{\mathcal{R}} \varphi_{N,L_N}(\mathbf{y}) d\mathbf{y}]^T$ and $\tilde{\mathcal{I}}_{\text{avg}}$ specifies the average illuminance constraint.

D. Optimization Problem and Proposed Solution

Considering the power and illumination constraints given by (20), (22), (28), and (30), and the CRLB expression specified by (8) and (17), we propose the following problem for optimizing the transmit powers of the LEDs:

$$\underset{\mathbf{w}}{\text{minimize trace}} \left\{ \left((\mathbf{I}_3 \otimes \sqrt{\mathbf{w}})^T \mathbf{H} (\mathbf{I}_3 \otimes \sqrt{\mathbf{w}}) \right)^{-1} \right\} \quad (31)$$

$$\text{subject to } \mathbf{w}^{\text{low}} \leq \mathbf{w} \leq \mathbf{w}^{\text{upp}} \quad (32)$$

$$\mathbf{B}\mathbf{w} \leq \mathbf{w}^{\text{tot}} \quad (33)$$

$$\sqrt{\mathbf{w}}^T \boldsymbol{\varphi}(\mathbf{y}_\ell) \geq \tilde{\mathcal{I}}_\ell, \ell \in \{1, \dots, M\} \quad (34)$$

$$\sqrt{\mathbf{w}}^T \bar{\boldsymbol{\varphi}}_{\mathcal{R}} \geq \tilde{\mathcal{I}}_{\text{avg}} \quad (35)$$

where $\boldsymbol{\varphi}(\mathbf{y}_\ell)$'s are defined as in (27) and $\bar{\boldsymbol{\varphi}}_{\mathcal{R}}$ is as in (30). The power constraints in (32) and (33) are linear. The illumination constraints in (34) and (35) are convex since the left hand sides of these constraints depend linearly on $\sqrt{\mathbf{w}}$, which is a concave function, and are lower bounded [36]. Hence, the illumination constraints specify convex sets. However, the objective function is not convex in general. Therefore, convex optimization techniques cannot directly be applied to this optimization problem to obtain its solution.

At this point, two main approaches can be considered to obtain a solution of (31)–(35). The first approach is to apply a global optimization algorithm such as particle swarm optimization (PSO) [37] to obtain a solution. However, the globally optimal solution is not guaranteed via this approach and it can have high complexity when the total number of LEDs is high. Therefore, an alternative approach is proposed as follows.

- 1) *Step 1:* Obtain the optimal transmit power parameters that maximize the total received power at the VLC receiver under the constraints in (32)–(35) based on a *convex* optimization problem.
- 2) *Step 2:* Use the solution of the power total maximization problem as the initial point for (31)–(35) and

implement a *constrained gradient descent* algorithm to obtain the solution.

The main idea behind the proposed algorithm is that maximizing the total received power at the VLC receiver can in general improve the localization accuracy [25, Sec. III]. Therefore, it can be considered to obtain a solution that achieves a close CRLB to that achieved by the solution of the original problem in (31)–(35). Hence, using the solution of the total received power maximization problem as an initial point, it can be possible to reach/approximate the solution of (31)–(35) via a gradient descent algorithm (although the globally optimal solution may not be guaranteed in all cases).

In Step 1 of the proposed approach, the aim is to maximize the total received power, which is given by

$$\sum_{i=1}^N \sum_{j=1}^{L_i} h_{i,j} \sqrt{w_{i,j}} \triangleq \sqrt{\mathbf{w}^T \mathbf{h}} \quad (36)$$

where $\mathbf{h} \triangleq [\mathbf{h}_1^T \cdots \mathbf{h}_N^T]^T$. Therefore, the following optimization problem is to be solved in Step 1:

$$\begin{aligned} & \underset{\mathbf{w}}{\text{maximize}} \quad \sqrt{\mathbf{w}^T \mathbf{h}} \\ & \text{subject to} \quad (32)–(35). \end{aligned} \quad (37)$$

It is noted that the objective function in (37) is a concave function of $\mathbf{w}$. Therefore, its maximization over the convex set of constraints in (32)–(35) leads to a convex optimization problem. Hence, this problem can be solved rapidly via convex optimization algorithms (e.g., interior point methods) to obtain its globally optimal solution [36].

Let $\mathbf{w}_{\text{init}}^*$ denote the solution of (37). Then, in Step 2 of the proposed approach, the problem in (31)–(35) is initialized with $\mathbf{w}_{\text{init}}^*$ and a constrained gradient descent algorithm is run for obtaining the solution. Before specifying the details of the proposed algorithm, the gradient of the objective function in (31) is presented in the following lemma:

Lemma: Let $C(\mathbf{x}, \mathbf{w})$ denote the objective function in (31), i.e., the CRLB expression. Then, the partial derivative of $C(\mathbf{x}, \mathbf{w})$ with respect to the ℓ th element of $\mathbf{w}$ is given by

$$\frac{\partial C(\mathbf{x}, \mathbf{w})}{\partial w_\ell} = \text{trace} \left\{ -\mathbf{J}^{-1}(\mathbf{x}) \frac{\partial \mathbf{J}(\mathbf{x})}{\partial w_\ell} \mathbf{J}^{-1}(\mathbf{x}) \right\} \quad (38)$$

where $\mathbf{J}(\mathbf{x})$ is as defined in (17) and $\frac{\partial \mathbf{J}(\mathbf{x})}{\partial w_\ell}$ is calculated as

$$\begin{aligned} \left[\frac{\partial \mathbf{J}(\mathbf{x})}{\partial w_\ell} \right]_{k_1, k_2} &= \frac{1}{2\sigma_m^2 \sqrt{w_{m, \ell - \sum_{i=1}^{m-1} L_i}}} \sum_{j=1}^{L_m} \sqrt{w_{m,j}} \\ &\times \left(\frac{\partial h_{m, \ell - \sum_{i=1}^{m-1} L_i}}{\partial x_{k_1}} \frac{\partial h_{m,j}}{\partial x_{k_2}} \right. \\ &\left. + \frac{\partial h_{m, \ell - \sum_{i=1}^{m-1} L_i}}{\partial x_{k_2}} \frac{\partial h_{m,j}}{\partial x_{k_1}} \right) \end{aligned} \quad (39)$$

if $\ell \in \{\sum_{i=1}^{m-1} L_i + 1, \dots, \sum_{i=1}^m L_i\}$ for $m \in \{1, \dots, N\}$, with $k_1, k_2 \in \{1, 2, 3\}$.

Proof: Since the CRLB is given by $C(\mathbf{x}, \mathbf{w}) = \text{trace}\{\mathbf{J}^{-1}(\mathbf{x})\}$, its partial derivative with respect to w_ℓ can

Algorithm 1:

- 1: Let ζ and T denote, respectively, the step size and the number of steps for gradient descent.
 - 2: Let $\mathcal{S}$ denote the set of $\mathbf{w}$ that satisfy (32)–(35).
 - 3: Solve (37) via an interior point algorithm [36] and obtain its solution denoted by $\mathbf{w}_{\text{init}}^*$.
 - 4: $\mathbf{w}^{(0)} \leftarrow \mathbf{w}_{\text{init}}^*$
 - 5: $\mathbf{w}_{\text{opt}} \leftarrow \mathbf{w}^{(0)}$
 - 6: **for** $t = 1$ to T **do**
 - 7: $\mathbf{w}^{(t)} \leftarrow \mathbf{w}^{(t-1)} - \zeta \nabla_{\mathbf{w}} C(\mathbf{x}, \mathbf{w}^{(t-1)})$
 - 8: **if** $\mathbf{w}^{(t)} \notin \mathcal{S}$ **then**
 - 9: $\mathbf{w}^{(t)} \leftarrow \arg \min_{\mathbf{w} \in \mathcal{S}} \|\mathbf{w}^{(t)} - \mathbf{w}\|$
 - 10: **end if**
 - 11: **if** $C(\mathbf{x}, \mathbf{w}^{(t)}) < C(\mathbf{x}, \mathbf{w}_{\text{opt}})$ **then**
 - 12: $\mathbf{w}_{\text{opt}} \leftarrow \mathbf{w}^{(t)}$
 - 13: **end if**
 - 14: **end for**
 - 15: Return $\mathbf{w}_{\text{opt}}$.
-

be expressed as in (38) [38]. Then, the partial derivative of $\mathbf{J}(\mathbf{x})$ with respect to w_ℓ can be obtained based on (11) after some manipulation as follows:

$$\begin{aligned} \left[\frac{\partial \mathbf{J}(\mathbf{x})}{\partial w_\ell} \right]_{k_1, k_2} &= \frac{1}{2\sigma_m^2 \sqrt{w_{m, \ell - \sum_{i=1}^{m-1} L_i}}} \\ &\times \left(\frac{\partial h_{m, \ell - \sum_{i=1}^{m-1} L_i}}{\partial x_{k_1}} \sum_{j=1}^{L_m} \sqrt{w_{m,j}} \frac{\partial h_{m,j}}{\partial x_{k_2}} \right. \\ &\left. + \frac{\partial h_{m, \ell - \sum_{i=1}^{m-1} L_i}}{\partial x_{k_2}} \sum_{j=1}^{L_m} \sqrt{w_{m,j}} \frac{\partial h_{m,j}}{\partial x_{k_1}} \right) \end{aligned} \quad (40)$$

if $\ell \in \{\sum_{i=1}^{m-1} L_i + 1, \dots, \sum_{i=1}^m L_i\}$ for $m \in \{1, \dots, N\}$ where $k_1, k_2 \in \{1, 2, 3\}$. Then, reorganizing the terms in the parentheses in (40) yields the expression in (39). $\square$

Based on (38) and (39) in the Lemma, the gradient of the objective function in (31) can be obtained as

$$\nabla_{\mathbf{w}} C(\mathbf{x}, \mathbf{w}) = \left[\frac{\partial C(\mathbf{x}, \mathbf{w})}{\partial w_1} \cdots \frac{\partial C(\mathbf{x}, \mathbf{w})}{\partial w_{\sum_{i=1}^N L_i}} \right]^T. \quad (41)$$

By using the gradient of the objective function, Algorithm 1 presented as follows is implemented to obtain a solution of (31)–(35).

The projection operation in line 9 of Algorithm 1 is performed to keep the solution in the feasible region, which is a common approach for constrained gradient descent algorithms called *projected gradient descent* [36]. It is noted that this projection operation corresponds to a convex optimization problem since $\mathcal{S}$ is a convex set and the objective function is convex.

The complexity of Algorithm 1 is mainly determined by the complexity of solving the convex optimization problems for projection (which occurs at most T times, with T denoting the number of steps in the gradient descent algorithm), and the calculations of the gradient in line 7 and the CRLB

in line 11 of Algorithm 1. In general, the CRLB and gradient calculations have lower computational complexity than the projection operation in line 9 since their complexity mainly depends on the complexity of 3×3 matrix inversion [see (31) and (38)], whereas the projection operation involves convex optimization over a $\sum_{i=1}^N L_i$ dimensional space with $\sum_{i=1}^N L_i$ being a large number in most practical cases (e.g., 16 in the simulations in Section IV). Considering the interior point method for solving the convex optimization problem, the projection operation has a worst case complexity of $\mathcal{O}((\sum_{i=1}^N L_i)^3)$.

E. Iterative Power Allocation and Localization for Practical Implementation

The optimization problem formulated and solved in Section III-D requires the knowledge of the location $\mathbf{x}$ of the VLC receiver, which is not available in practice. For *tracking* applications, the position estimate of the VLC receiver in the previous time step can be employed to implement the proposed algorithm (Algorithm 1). Then, the obtained power parameter vector $\mathbf{w}$ can be used to transmit signals from the LEDs [see (1)] and the resulting received powers, denoted by $P_{RX,1}, \dots, P_{RX,N}$, are observed as in (4). Based on these received powers, the ML estimator, which can be obtained from (7), is implemented as follows:

$$\hat{\mathbf{x}} = \arg \min_{\mathbf{x}} \sum_{i=1}^N \frac{1}{\sigma_i^2} \left(P_{RX,i} - \sum_{j=1}^{L_i} h_{i,j} \sqrt{w_{i,j}} \right)^2$$

$$\triangleq \arg \min_{\mathbf{x}} \tilde{G}(\mathbf{P}_{RX}, \mathbf{w}) \quad (42)$$

where $h_{i,j}$ is a function of $\mathbf{x}$ as specified in (6), $w_{i,j}$'s correspond to the elements of $\mathbf{w}$; that is, $\mathbf{w} = [w_{1,1} \dots w_{1,L_1} \dots w_{N,1} \dots w_{N,L_N}]^T$, and $\mathbf{P}_{RX} = [P_{RX,1} \dots P_{RX,N}]^T$, as defined before.

In the absence of tracking (i.e., without any prior knowledge about the position of the VLC receiver), localization and power allocation can be performed in an iterative manner by implementing the following N_S -step algorithm, called Algorithm 2.

For the random initialization of the power parameter vector in Algorithm 2, one reasonable choice can be uniform (equal) power allocation, i.e., $w_{i,j} = w_i^{\text{tot}}/L_i$ for $j = 1, \dots, L_i$ and $i = 1, \dots, N$ if it is feasible [that is, if it satisfies (32)–(35)]. Also, as the noise variances decay to zero, the performance of the position estimator in Algorithm 2 is expected to converge, in a few iterations, to that of the ML estimator which is based on the power parameter vector obtained by assuming the knowledge of the position of the VLC receiver (i.e., obtained via Algorithm 1). This expectation stems from the asymptotic optimality properties of the ML estimator [25], [35].

Remark 1: The proposed iterative algorithm adapts the transmit power parameters at the frequency of the navigation loop. While rapid changes in optical power can theoretically introduce perceptible flicker, the proposed framework

Algorithm 2:

- 1: **for** $k = 1$ to N_S **do**
- 2: **if** $k = 1$ **then**
- 3: Set $\mathbf{w}$ randomly to a point $\mathbf{w}^{(1)}$ in feasible region specified by (32)–(35).
- 4: **else**
- 5: Use $\hat{\mathbf{x}}^{(k-1)}$ as VLC receiver position and implement Algorithm 1 to obtain the power parameters, which are denoted by $\mathbf{w}^{(k)}$.
- 6: **end if**
- 7: Transmit signals from the LED arrays according to the power parameters in $\mathbf{w}^{(k)}$ [see (1)]. Let the corresponding received powers in (4) be denoted by $\mathbf{P}_{RX}^{(k)} = [P_{RX,1}^{(k)}, \dots, P_{RX,N}^{(k)}]$.
- 8: Implement the ML estimator for the position of the VLC receiver based on $\mathbf{P}_{RX}^{(k)}$ and $\mathbf{w}^{(k)}$ as follows:

$$\hat{\mathbf{x}}^{(k)} = \arg \min_{\mathbf{x}} \tilde{G}(\mathbf{P}_{RX}^{(k)}, \mathbf{w}^{(k)}) \quad (43)$$

with $\tilde{G}(\cdot)$ being defined as in (42).

- 9: **end for**
 - 10: Return $\mathbf{w}_{\text{opt}}$ and $\hat{\mathbf{x}}^{(N_S)}$.
-

mitigates this through two mechanisms. First, in practical navigation scenarios, the receiver's physical location changes continuously rather than abruptly; consequently, the optimal power allocation vector evolves smoothly over consecutive iterations, minimizing sudden intensity jumps. Second, the optimization problem explicitly enforces lower bound constraints and minimum illumination requirements, ensuring that LEDs never enter an off-state during operation, thereby preventing flickering. $\square$

Since Algorithm 2 employs Algorithm 1 in each iteration, its complexity burden on the VLP system for setting the parameters of the LED arrays is $(N_S - 1)$ times that of Algorithm 1 (-1 is due to the use of the random (or, uniform) power allocation approach in the initial step). Consequently, the overall worst case computational complexity for the power allocation updates corresponds to $\mathcal{O}((N_S - 1)(\sum_{i=1}^N L_i)^3)$. On the other hand, the ML estimator is implemented at the VLC receiver as in (43), solving which requires a 3-D search over the indoor environment. (Since $\tilde{G}$ is not a convex function of $\mathbf{x}$, exhaustive search with a certain resolution can be performed.) It should also be noted that the VLC receiver informs the VLP network about its ML position estimate so that the power allocation can be optimized for the next iteration.

IV. SIMULATION RESULTS

In this section, we conduct simulations for illustrating the improvements achieved through the proposed power allocation approach and the iterative power allocation and localization approach. The indoor localization environment considered in the simulations is a room with dimensions $20 \times 20 \times 5 \text{ m}^3$, where the lower left corner of the

Fig. 2. VLP system considered in the simulations, where there exist four LED arrays each consisting of four LEDs. The VLC receiver is placed at two different locations in Scenarios 1 and 2 as shown in the figure. The dashed lines are used to illustrate the orientation vectors of the LEDs more clearly.

room is considered as the origin, $[0\ 0\ 0]^T$, as shown in Fig. 2. There exist $N = 4$ LED arrays on the ceiling of the room, which are centered at $[5\ 5\ 5]^T$ m, $[15\ 5\ 5]^T$ m, $[5\ 15\ 5]^T$ m, and $[15\ 15\ 5]^T$ m for LED arrays 1, 2, 3, and 4, respectively. Each LED array consists of four LEDs, i.e., $L_i = 4$ for $i = 1, 2, 3, 4$. The four LEDs in each array are placed with a distance of ± 5 cm with respect to the center of the LED array in the x - and y -directions. In particular, the locations of the LEDs in LED array 1 are $\mathbf{l}_{1,1} = [5.05\ 5.05\ 5]^T$, $\mathbf{l}_{1,2} = [5.05\ 4.95\ 5]^T$, $\mathbf{l}_{1,3} = [4.95\ 5.05\ 5]^T$, and $\mathbf{l}_{1,4} = [4.95\ 4.95\ 5]^T$ m. Similarly, the locations of the LEDs in LED array 2 are $\mathbf{l}_{2,1} = [15.05\ 5.05\ 5]^T$, $\mathbf{l}_{2,2} = [15.05\ 4.95\ 5]^T$, $\mathbf{l}_{2,3} = [14.95\ 5.05\ 5]^T$, and $\mathbf{l}_{2,4} = [14.95\ 4.95\ 5]^T$ m, those in LED array 3 are $\mathbf{l}_{3,1} = [5.05\ 15.05\ 5]^T$, $\mathbf{l}_{3,2} = [5.05\ 14.95\ 5]^T$, $\mathbf{l}_{3,3} = [4.95\ 15.05\ 5]^T$, and $\mathbf{l}_{3,4} = [4.95\ 14.95\ 5]^T$ m, and those in LED array 4 are $\mathbf{l}_{4,1} = [15.05\ 15.05\ 5]^T$, $\mathbf{l}_{4,2} = [15.05\ 14.95\ 5]^T$, $\mathbf{l}_{4,3} = [14.95\ 15.05\ 5]^T$, and $\mathbf{l}_{4,4} = [14.95\ 14.95\ 5]^T$ m. It is noted that the LED arrays are placed at the centers of the four $10\text{ m} \times 10\text{ m}$ squares that divide the ceiling of the room into four equal areas. The orientation vectors of the LEDs in the LED arrays are arranged such that each LED is pointed toward the closest of the 16 points which correspond to the centers of the $5\text{ m} \times 5\text{ m}$ squares on the floor shown in Fig. 2. For example, the LED at location $\mathbf{l}_{1,1} = [5.05\ 5.05\ 5]^T$ m is oriented towards $[7, 5\ 7.5\ 0]^T$ m. Due to the symmetry, the LEDs in each array have the same set of four orientation vectors, which can be calculated as $\mathbf{n}_{i,1} = [0.4028\ 0.4028\ -0.8219]^T$, $\mathbf{n}_{i,2} = [0.4028\ -0.4028\ -0.8219]^T$, $\mathbf{n}_{i,3} = [-0.4028\ 0.4028\ -0.8219]^T$, and $\mathbf{n}_{i,4} = [-0.4028\ -0.4028\ -0.8219]^T$ for $i = 1, 2, 3, 4$. The setup of the LED arrays is illustrated in Fig. 2, where the dashed lines are used to demonstrate the orientations of the LEDs.

To investigate the performance of the proposed approaches in different conditions, we consider two scenarios for the location of the VLC receiver. In Scenario 1, the VLC receiver is placed at $\mathbf{x} = [14\ 6.3\ 1.9]^T$ m while

TABLE I
Simulation parameters [17], [39], [40]

Responsivity of photodetector, R_p	0.4 mA/mW
Area of photodetector, A	1 cm ²
Noise spectral density level, σ^2	10^{-15} W/Hz
LED Lambertian order, $m_{i,j} \forall i, j$	1
LED luminous efficacy, $\kappa_{i,j} \forall i, j$	284 lm/W
Min. LED optical power parameter, $w_{i,j}^{\text{low}} \forall i, j$	5 W
Max. LED optical power parameter, $w_{i,j}^{\text{upp}} \forall i, j$	20 W
Individual illuminance limit, $\tilde{I}_\ell, \ell = 1, 2, 3, 4$	30 lx
Average illuminance limit, $\tilde{I}_{\text{avg}}$	30 lx

it is at $\mathbf{x} = [5\ 5\ 1]^T$ m in Scenario 2. In both scenarios, the orientation vector of the VLC receiver is given by $\tilde{\mathbf{n}} = [0\ 0\ 1]^T$, i.e., it has a perpendicular orientation. The location and the orientation of the VLC receiver are shown in Fig. 2 for each scenario. Since the LEDs in the LED arrays have various locations and orientations, some of them may not be in the FOV of the VLC receiver in a given scenario. Specifically, in Scenario 1, the j th LED of the i th LED array is not in the FOV of the VLC receiver if $(i, j) \in \{(1, 3), (1, 4), (3, 3), (4, 1), (4, 3)\}$ while all the other LEDs are in the FOV. Similarly, the LEDs that are not in the FOV of the VLC receiver in Scenario 2 are specified by indices $(i, j) \in \{(2, 1), (2, 2), (3, 1), (3, 3), (4, 1)\}$, where i and j denote the indices of the LED array and the LED, respectively. Regarding the individual illumination constraints in (34), $M = 4$ locations are specified as $\mathbf{y}_1 = [5\ 5\ 1]^T$ m, $\mathbf{y}_2 = [15\ 5\ 1]^T$ m, $\mathbf{y}_3 = [5\ 15\ 1]^T$ m, and $\mathbf{y}_4 = [15\ 15\ 1]^T$ m. Hence, certain illumination levels should be guaranteed at these four locations. On the other hand, the average illumination of the room is computed as specified in (29) and the computation is performed over the horizontal plane of the room the height of which is set at 1 m. Moreover, in accordance with [17], [39], and [40], the VLP system parameters employed in the simulations are given in Table I.

In the simulations, the total power constraints for the LED arrays are taken to be equal, i.e., $w_i^{\text{tot}} = w^{\text{tot}}$, for $i = 1, 2, 3, 4$. To provide a comparative performance evaluation of , the transmit power parameters are calculated based on the following three approaches:

- 1) uniform (equal) transmit power parameters (i.e., $w_{i,j} = w^{\text{tot}}/L_i$ for $i, j = 1, 2, 3, 4$);
- 2) power maximization approach in (35), which is solved via CVX in MATLAB;
- 3) Algorithm 1 specified in Section III-D.

Then, the CRLBs achieved by using these transmit power parameters are obtained. In addition, the root-mean squared errors (RMSEs) of the ML estimators in (42) are calculated when the transmit power parameters obtained from these three approaches are used. Figs. 3 and 4 illustrate the CRLBs and the RMSEs of the ML estimators for these three approaches versus w^{tot} considering the two scenarios for the location of the VLC receiver. Algorithm 1 utilizes a convergence criterion to determine the optimal stopping point. The iterative process terminates when the relative decrease in the CRLB between consecutive steps falls below

TABLE II
Transmit Power Parameters Obtained From the Power Maximization Approach and Algorithm 1 for Scenario 1

a predefined tolerance of $\epsilon = 2 \times 10^{-3}$ (i.e., less than 0.2% improvement). Table III summarizes the convergence behavior, reporting the number of iterations and total runtime required to meet this criterion for varying power constraints. The results demonstrate rapid convergence, with the algorithm typically requiring less than or equal to 20 iterations and executing in subsecond time frames. All simulations were performed on a standard personal computer equipped with an Intel Core i7 processor and 16 GB of RAM. It is important to note that the reported run times include significant parsing and modeling overhead from the CVX framework. Since CVX is optimized for flexibility and ease of implementation rather than execution speed, these values represent a conservative upper bound on computational complexity. In practical deployments, replacing CVX with

TABLE III
Runtimes and the Number of Gradient Steps Before Convergence of Algorithm 1 for Scenario 1

Total Power Constraint (w^{tot})	Step 2: Refine (Projected Gradient)	Total Runtime (s)
30.00 W	12	0.722 s
40.00 W	20	0.639 s
50.00 W	20	0.539 s
60.00 W	16	0.625 s
70.00 W	10	0.392 s
80.00 W	3	0.371 s
Average	13.5	0.548 s

TABLE IV
Average Runtimes and Average Number of Gradient Steps of Algorithm 1 for Different Numbers of LEDs in the Network

Network Size ($N \times L_s$)	Total Variables	Avg. Gradient Steps	Avg. Total Runtime (s)
16 LEDs (4×4)	16	13.3	0.548 s
32 LEDs (4×8)	32	19.6	0.685 s
64 LEDs (4×16)	64	21.5	0.983 s

optimized, low-level solvers (e.g., C/C++) would eliminate this bottleneck, substantially reducing execution time.

To evaluate scalability, Table IV presents the average runtime and convergence behavior for increasing network sizes. The results demonstrate favorable computational scaling: quadrupling the number of optimization variables (from 16 to 64 LEDs) increases the average runtime by less than a factor of two (from 0.548 s to 0.983 s). This confirms that the proposed algorithm remains computationally efficient and feasible even for dense VLP deployments.

Fig. 3 demonstrates that when the VLC receiver is placed as in Scenario 1, the proposed approach can yield substantial enhancements in comparison to the power optimization approach and the conventional uniform power allocation approach in terms of both the CRLB and ML estimation performance.² These enhancements are more pronounced at higher values of w^{tot} since all the approaches yield the same result of assigning 5 to all the transmit power

²Since the possible locations for the VLC receiver within the room are constrained to a volume of $20 \times 20 \times 5 \text{ m}^3$, the ML estimator conducts a search within this designated space. On the other hand, the CRLB derivations do not presume any a-priori knowledge about the location of the VLC receiver. Hence, the RMSEs of the ML estimator may be lower than the CRLBs in noisy cases as in Fig. 3.

TABLE V
Transmit Power Parameters Obtained From the Power Maximization Approach and Algorithm 1 for Scenario 2

	$(w_{1,1}, w_{1,2}, w_{1,3}, w_{1,4})$	$(w_{2,1}, w_{2,2}, w_{2,3}, w_{2,4})$	$(w_{3,1}, w_{3,2}, w_{3,3}, w_{3,4})$	$(w_{4,1}, w_{4,2}, w_{4,3}, w_{4,4})$
Power max., $w^{\text{tot}} = 40$	(10, 10, 10, 10)	(5, 5, 15, 15)	(5, 15, 5, 15)	(5, 7.5, 7.5, 20)
Algorithm 1, $w^{\text{tot}} = 40$	(10, 10, 10, 10)	(5, 5, 15, 15)	(5, 15, 5, 15)	(5, 7.5, 7.5, 20)
Power max., $w^{\text{tot}} = 60$	(15, 15, 15, 15)	(9.15, 9.12, 20, 20)	(9.15, 20, 9.12, 20)	(5, 17.5, 17.5, 20)
Algorithm 1, $w^{\text{tot}} = 60$	(15, 15, 15, 15)	(9.15, 9.12, 20, 20)	(9.15, 20, 9.12, 20)	(5, 17.5, 17.5, 20)

The transmit parameters of the LEDs that are not in the FOV of the VLC receiver in Scenario 2 are indicated with blue color.

parameters when $w^{\text{tot}} = 20$ (since $w_{i,j}^{\text{low}} = 5$ and $w_{i,j}^{\text{upp}} = 20$ for all i, j). From the results in Fig. 3, it is inferred that maximizing the received power at the VLC receiver location does not always lead to the optimal localization performance. For further elaboration, Table II presents the transmit power parameters obtained from the power maximization approach and Algorithm 1 for Scenario 1 when w^{tot} is set to 40 and 60. Upon the examination of the values in the table, it is observed that although both of the approaches yield similar values for LED array 1, LED array 3, and LED array 4, the transmit power parameters for LED array 2 are significantly different. It is noted that LED array 2 is the closest LED array to the VLC receiver in Scenario 1. The proposed approach (Algorithm 1) prioritizes maximizing the transmit power parameter of the second LED of that array over others, while ensuring that the transmit power parameters of the first and third LEDs of the array are maintained at their minimum. It is important to note that when $w^{\text{tot}} = 60$, the transmit power parameter set for LED array 2 is (5, 20, 5, 20) according to Algorithm 1, resulting in a total power of 50, which is lower than the specified total power constraint of 60. The underlying cause of this phenomenon can be attributed to the fact that the efficacy of the localization process is contingent upon the power sensitivity of the power measurements with respect to the location of the VLC receiver; hence, it depends on the partial derivatives in (12). Since these partial derivatives can have opposite signs for different LEDs in a given array, increasing the power of an LED can sometimes have a destructive effect on the localization performance [25]. Due to this behavior, the proposed approach (Algorithm 1) converges to its optimal value at around $w^{\text{tot}} = 50$. Increasing the total power constraint above this level does not significantly improve the CRLB as seen in Fig. 3. In Table II, the transmit power parameters of the LEDs that are not in the FOV of the VLC receiver in Scenario 1 are marked with blue color. In most cases, the minimum transmit power parameter of 5 is assigned to those LEDs. However, when $w^{\text{tot}} = 60$ and the transmit power parameters of the other LEDs are at the maximum level of 20, the LEDs outside the FOV can be assigned any transmit power parameter value within the feasible region (for example, [5, 10] for $w_{1,3}, w_{1,4}, w_{4,1}, w_{4,3}$) as these LEDs do not affect the CRLB value. Hence, the transmit power parameters presented in the table for those LEDs do not correspond to unique solutions.

It is also possible that the performance of the proposed approach (Algorithm 1) can be equivalent to the power maximization approach in certain instances, as illustrated in Fig. 4, where the location of the VLC receiver is set as in

Fig. 5. RMSEs of the ML estimators corresponding to uniform, power maximization, and the two proposed power allocation strategies (Algorithms 1 and 2) with respect to w^{tot} for Scenario 1.

Fig. 6. RMSEs of the ML estimators corresponding to uniform, power maximization, and the two proposed power allocation strategies (Algorithms 1 and 2) with respect to w^{tot} for Scenario 2.

Scenario 2. In this scenario, maximizing the received power at the VLC receiver is equivalent to CRLB minimization and yields the optimal solution. Table V provides the transmit power parameters obtained from the power maximization approach and Algorithm 1 for Scenario 2 with w^{tot} being set to 40 and 60. As demonstrated in the table, it is evident that the two approaches result in the same transmit power parameters. However, they still demonstrate superiority over the uniform power allocation as noted from Fig. 4. Also, similar to Table II, the transmit power parameters of the LEDs that are not in the FOV of the VLC receiver in Scenario 2 are marked with blue color in Table V, and $w_{2,1}, w_{2,2}, w_{3,1}, w_{3,3}$ are not unique for $w^{\text{tot}} = 60$.

Figs. 5 and 6 illustrate the RMSE values of the ML estimators implemented in the iterations of Algorithm 2

along with the RMSEs of the ML estimators of Algorithm 1 (the case of known VLC receiver location) with respect to w^{tot} for the two scenarios. It is observed from these figures that, despite the initial position of the receiver being unknown in Algorithm 2, the results produced by it are comparable to those of Algorithm 1 after a few iterations. Fig. 5, which corresponds to Scenario 1, demonstrates that the performance of Algorithm 2 gets very close to that of Algorithm 1 in the third iteration. Notably, even in the second iteration, a substantial enhancement in the performance of the proposed method (Algorithm 2) is evident when compared to both the uniform power allocation and power maximization approaches. On the other hand, as illustrated in Fig. 6, when the location of the VLC receiver is as in Scenario 2, the performance of Algorithm 2 converges to that of Algorithm 1 in the second iteration. The third iteration is omitted from the figure since convergence is already achieved in the second iteration. In summary, Algorithm 2 is shown to provide a viable solution for practical cases in which the location of the VLC receiver is unknown. These results demonstrate the practicability and efficacy of the proposed approach, suggesting its potential for successful implementation in practical settings.

V. CONCLUDING REMARKS

In this manuscript, we presented a power allocation framework for asynchronous VLP systems using LED arrays, with consideration of practical power and illumination constraints. The proposed approach involved the formulation and solution of a constrained optimization problem for minimizing the CRLB for the receiver location while satisfying the constraints imposed by illumination requirements and power limitations. Our two-step algorithm, which first maximizes the total received power via convex optimization, and then, refines the power parameters with a projected gradient descent approach, proved effective and practical, especially when integrated with an iterative localization procedure. Simulation results confirmed that the proposed power allocation strategy consistently attains superior positioning accuracy in comparison to uniform or purely power-based methods, illustrating its significance for indoor localization applications.

As possible directions for future work, effects of multipath reflections can be considered and experiments based on real data can be conducted for investigating effects of hardware imperfections. Also, a misspecified CRLB analysis can be performed for taking hardware imperfections into account.

Ramazan Yaz received the B.S. degree in electrical and electronics engineering in 2022 from the Department of Electrical and Electronics Engineering, Middle East Technical University, Ankara, Türkiye, and the M.S. degree in electrical and electronics engineering in 2025 from the Department of Electrical and Electronics Engineering, Bilkent University, Ankara, where he is currently working toward the Ph.D. degree in electrical and electronics engineering.

His current research interests include signal processing, wireless localization, and visible light positioning systems.

Sinan Gezici received the B.Sc. degree in electrical and electronics engineering from Bilkent University, Ankara, Turkey, in 2001, and the Ph.D. degree in electrical engineering from Princeton University, Princeton, NJ, USA, in 2006.

From 2006 to 2007, he worked with Mitsubishi Electric Research Laboratories, Cambridge, MA, USA. Since 2007, he has been with the Department of Electrical and Electronics Engineering, Bilkent University, where he is currently a Professor. He is the author the book titled *Ultra-wideband Positioning Systems: Theoretical Limits, Ranging Algorithms, and Protocols* (Cambridge University Press, 2008). His research interests include the areas of detection and estimation theory, wireless communications, and localization systems.

Dr. Gezici has been an Associate Editor for *IEEE TRANSACTIONS ON VEHICULAR TECHNOLOGY*, *IEEE TRANSACTIONS ON COMMUNICATIONS*, *IEEE WIRELESS COMMUNICATIONS LETTERS*, and *Journal of Communications and Networks*.
